

How can the public be persuaded to accept vaccine passports?

Vaccine passports can be unpopular. Researchers from Bocconi, LSE and Yale carried out two experiments to explore how governments could persuade people of their merits.

Once called “[the next political flashpoint](#)” in the COVID [culture wars](#), vaccine passports continue to spark controversy in the United States and worldwide. These ‘passports’ are electronic or paper vaccination certificates that allow vaccinated people to do certain things that the unvaccinated can’t. Some of them are “international”. For example, the European Commission has reached an agreement on the “[Digital COVID Certificate](#)”, which will provide proof that a person has been vaccinated against COVID, received a negative test result, or recently recovered from the virus. Others are “domestic”: some countries like [Israel](#), [Chile](#) and [France](#) go as far as requiring proof of vaccination to take part in ordinary activities like attending shows or even circulating freely during general lockdowns.

If polarisation around the pandemic is bad enough, polarisation around vaccine passports is worse. Remember what happened with contact tracing apps: once presented as key to return to some kind of normalcy, they were ultimately doomed because people didn’t trust them. Vaccine passports could suffer the same fate. Although more coercive than contact tracing apps, their success ultimately depends on public support and cooperation. Imposing them on a sceptical public could trigger resistance, induce forgery, or even – as some preliminary research [suggests](#) – increase vaccine hesitancy. If vaccine passports are to be introduced at all, they had better enjoy public support.

We conducted [two experiments](#) to test whether some well-known behavioural tools could be used to increase support for passports while not decreasing vaccine uptake, nor furthering polarisation. Our results are heartening and suggest these techniques could be used to nudge people into other socially beneficial behaviours, while keeping polarisation at bay.

In [our first experiment](#), we leveraged the [status quo bias](#) (that is, the tendency people have towards accepting a situation once it is framed as being the status quo rather than a change). In fact, immunity passports can easily be presented as not that much of a new idea. To travel to certain countries one has to show a [yellow card](#) – a World Health Organization-sponsored proof of vaccination against yellow fever. Domestic restrictions for the unvaccinated are also not radically innovative: schools and universities – even [the most libertarian](#) among them! – routinely ask for a list of mandatory vaccines to be on campus.

We ran two parallel survey experiments, one for the “international” passport and one for the “domestic” one (each with approximately 1,600 US American residents, recruited through Prolific.co in a non-representative sample). We randomly assigned half of respondents in each category to a control group and to a “status quo” group. To each control group, we explained the Covid Pass policy. To each status quo group, in addition, we showed that the passport was not a novel idea, using the examples of the yellow card and of universities respectively.

Figure 1: The explanation of the COVID Pass, with the yellow card example

What is a COVID PASS?

A COVID PASS would be a printed card or an app allowing the holder to easily show that they are vaccinated against COVID-19 or that they have recently recovered from the virus.

Why have a COVID pass?

Many airline companies and are starting to require a pro vaccination from their customers. Without a proof of vaccination people will not to **board flights operated by companies or to visit these**

A COVID PASS would allow people provide a **quick and certified** vaccination.

Many experts believe that introduction of the COVID Pass facilitate international travel help boosting the tourism while reducing the risk that variants of COVID-19 originate other countries will reach t

All the results were in the direction we anticipated. In both cases, the status quo group showed higher support for the pass than the control group. Furthermore, the status quo group stated a higher willingness to vaccinate than the control group. Finally, and perhaps most interestingly, the status quo treatment seems to have reduced polarisation between Democrats and Republicans (defined as the distance between their respective opinions towards the passport). This reduction seems to have worked mostly through softening conservatives' opposition, which is [consistent with the literature](#). The decrease was larger for the domestic pass, which could be explained by the fact that the treatment made explicit that both conservative and liberal institutions have required immunisation proof in the past. All our results are robust to a battery of controls and significant to the 1%.

In our second experiment, we built on the (quite incipient) literature on [interaction among nudges](#) to test whether two nudges could work together – or whether, as some authors suggest, they would “crowd each other out,” making them ineffective or even counterproductive. Again, we ran a survey experiment with 4,000 US residents, this time focusing only on international passports. We divided respondents evenly into four groups. To the control group, we showed the “international Covid pass” policy, and to the first treatment group we replicated the “status quo” treatment from the previous experiment. To the second treatment group, we leveraged the “peer effect,” telling respondents that only one third of Americans oppose immunity passports for international travel. Finally, we exposed the fourth group to both these treatments at once.

We observe that both nudges are effective in increasing the support for the pass, and they do not fuel vaccine hesitancy. Furthermore, we observe that their combined impact is stronger than any of them individually. In the case of vaccine passports, this suggests that policymakers would be well advised to use both these nudges simultaneously. Indeed, the finding that these two nudges are weakly additive suggests that they could also be used in other policy areas.

This post represents the views of the authors and not those of the COVID-19 blog, nor LSE.
