Abstract
We present evidence on the labor supply of CEOs, and on whether family and professional CEOs differ on this dimension. We do so through a new survey instrument that allows us to codify CEOs' diaries in a detailed and comparable fashion, and to build a bottom-up measure of CEO labor supply. The comparison of 1,114 family and professional CEOs reveals that family CEOs work 9% fewer hours relative to professional CEOs. Hours worked are positively correlated with firm performance, and differences between family and non-family CEOs account for approximately 18% of the performance gap between family and non-family firms. We investigate the sources of the differences in CEO labor supply across governance types by exploiting firm and industry heterogeneity, and quasi-exogenous meteorological and sport events. The evidence suggests that family CEOs value–or can pursue–leisure activities relatively more than professional CEOs.

1 Introduction

The debate over the desirability of the separation between firm ownership and control is as old as the firm itself. Should firms be led by their owners or by professional managers? One of the main arguments in favor of owners is that they have more at stake, and are thus expected to exert more effort at work. This is the standard prediction of the principal-agent model, as owners are residual claimants over the income generated by the business and hence are motivated to succeed, other things equal. The argument against is that, simply put, other things are not equal. For example, CEOs with a significant ownership stake on the firm are likely to be wealthier than professional CEOs–if leisure is a normal good, they may therefore demand more leisure.[1] Equivalently, owner CEOs may be able to pursue private interests at the expense of other stakeholders (Shleifer and Vishny (1989))–if the pursuit of private interests crowds out activities that are beneficial to the firm, this will also result in less managerial effort. These factors may lead to owner CEOs being *less* motivated to work hard relative to non-owners.

Family CEOs–i.e. managers with a majority ownership stake in the firm, who have either founded the firm, or inherited the firm from the original founders–are a primary example of owner CEOs and are widely present in both developed and developing countries (Caselli and Gennaioli (2013), LaPorta et al. (1999)). In this paper, we explore differences between family and professional CEOs (i.e., non family affiliated CEOs) in one basic metric of effort: the number of hours they work. We do so using a new survey instrument, which allows us to codify the diaries of 1,114 CEOs of manufacturing firms across six countries: Brazil, France, Germany, India, the United Kingdom and the United States. To measure the labor supply of CEOs, we reconstruct their time diaries via daily phone interviews over the course of one week. We ask respondents (the CEOs themselves or their personal assistants) to list sequentially all activities in their diaries longer than fifteen minutes and to report details of those activities. This methodology allows us to build an accurate bottom-up estimate of how much time CEOs allocate to business activities. Our methodology is inspired by Mintzberg (1973) celebrated analysis of the work week of five CEOs, extended to large random samples.[2]

We find that there is substantial variation in the number of hours CEOs devote to work activities: the average CEO in our sample spends 52 hours per week (10.4 hours per day) at work, while CEOs in the bottom quartile work on average 44.2 hours per week, and those in the top quartile work

[1] For example, Holtz-Eakin et al. (1993) show that large inheritances reduce labor force participation and labor supply.

[2] "Shadowing" exercises are common in the management literature but typically cover a handful of observations. To the best of our knowledge, the most extensive CEO time use study is still Mintzberg (1973) seminal work, which comprises five CEOs. The largest observational dataset on top executives known to us –Kotter (1999)– includes 15 general managers. The largest time use study of managerial personnel we are aware of is Luthans (1988), which covers 44 mostly middle managers. Some surveys ask large numbers of CEOs general questions about their aggregate time use (e.g. McKinsey (2013), but they are not based on an analysis of their agendas for a specific time period. Karolyi and Liao (2015) collect data on the time spent by CEOs and CFOs in investor relations activities at 800 firms in 59 countries.

on average 58.5 hours per week. When we divide CEOs between family and professional CEOs–i.e. managers who do not have significant ownership stakes in the firm–we find a large difference in hours worked: family CEOs, who account for 41% of our sample, record 6 fewer hours per week relative to professional CEOs.

Are these differences correlated with firm performance, and in particular with differences in firm performance between family and professional CEOs? To answer this question, we match the CEO survey with accounting data. We show three related facts. First, CEO hours worked are positively and significantly correlated with firm performance: a one standard deviation change in CEO hours worked is associated with a 8% increase in firm productivity. Second, firms run by family CEOs are on average less productive (and profitable) than firms run by professional CEOs. Third, differences in CEO hours worked account for up to 18% of the performance gap between family and professional CEOs.

We develop a simple model of CEO labor supply to study why family and professional CEOs vary in their effort at work. The model illustrates that the observed cross sectional differences in hours worked across CEOs may depend on both differences in the marginal product of CEO effort across governance types–i.e. differences in CEO or firm characteristics that may make it uniquely optimal for family CEOs to work fewer hours–and differences in the CEO taste for leisure.

We assess the empirical relevance of these two alternative sources of variation by examining whether the gap in hours worked between family and professional CEOs can be accounted for by observable industry, firm and CEO characteristics which are likely to affect the marginal product of CEO effort. The data suggest that these factors do not fully account for differences in hours worked between family and professional CEOs. Once we include the full set of firm, CEO, and industry controls, family CEOs still work 9% fewer hours than their professional counterparts. Importantly, we observe that professional CEOs who run family firms work as much as their counterparts in non-family firms, suggesting that the difference in hours worked is not due to family ownership *per se*.

We then turn to analyze whether the difference in behavior observed in the data are consistent with heterogeneous preferences for leisure across CEOs. We do so by exploiting a key insight provided by the model: if family CEOs choose to work fewer hours because they put a higher weight on leisure relative to firm performance, then factors affecting the opportunity cost of leisure (or, symmetrically, the marginal cost of effort) across all CEOs should have a greater impact on family CEOs. To implement the empirical strategy suggested by the model, we study whether the difference in hours worked by family and professional CEOs varies with factors affecting the opportunity cost of leisure *across firms*, and *across days* of work. We use two alternative measures to proxy for differences in the opportunity cost of leisure across firms: firm size and the competitiveness of the industry in which the firm operates. The opportunity cost of leisure is likely to be higher in

larger firms, as CEOs' effort affects a larger volume of activity.[3] The opportunity cost of leisure is also likely to be higher in more competitive industries conditional on firm size, since competition lowers the probability of survival and increases the importance of managerial effort to keep the firm in business. We show that the difference in hours worked between family and professional CEOs is significantly smaller in larger firms and in firms active in more competitive industries. Furthermore, for two countries in our sample, India and Brazil, we are also able to measure variation in the opportunity cost of labor *across days*, using daily variation in rainfall and the broadcasting of popular sport events (Premier League cricket matches in India and State Football League matches in Brazil). In this sub-sample, the difference between family and professional CEOs is significantly larger on days when torrential rains or popular sport matches increase the marginal cost of effort.

Taken together, these results are consistent with the notion that family CEOs have different preferences for leisure relative to professional CEOs. We speculate that the heterogeneity in preferences across CEOs could be related to wealth effects–namely, by the fact that family CEOs may be wealthier than professional CEOs thanks to their ownership stake in the firm–and investigate this hypothesis by exploiting cross country differences in inheritance laws facilitating the intergenerational concentration of wealth.

While the cross sectional nature of our data limits our ability to make causal statements about the relationship between CEO hours worked and firm performance, the evidence is consistent with the idea that family CEOs may be willing to trade-off profits for other non-monetary benefits of control, such as the ability to enjoy more leisure (Demsetz and Lehn (1985), Bandiera et al. (2015)). Our findings complement the observation that family CEOs are less likely to adopt managerial best practices (Bloom and Van Reenen (2007), Lemos and Scur (2017)) and are characterized by a management style that is less conducive to shareholder value maximization (Mullins and Schoar (2013)). In line with these literatures, our time use analysis shows that the incentives arising from having a higher stake in the firm may be offset by other factors that induce less effort on the part of the CEOs. More broadly, our research illustrates one channel through which CEOs may affect firm performance (Bertrand and Schoar (2003), Kaplan et al. (2012), Malmendier and Tate (2005), Malmendier and Tate (2009), Schoar and Zuo (2011)). Finally, the paper is related to the strand of work emphasizing the importance of preferences in explaining differences in managerial effort (Bertrand and Mullainathan (2003), Malmendier and Tate (2009)).

The paper is organized as follows. Section 2 describes our sampling and data collection methodology, together with the characteristics of CEOs and their firms. Section 3 discusses differences in hours worked across family and professional CEOs, as well as the relationship between firm performance and CEO hours worked. Section 4 provides a simple model of CEO labor supply to guide the empirical analysis. Section 5 estimates the difference between family and professional CEOs

[3]This is analogue to the "scale of operations" effect discussed in Mayer (1960), which has been used to explain how small differences in ability can produce large differences in pay when more able CEOs work for larger firms, see e.g. Tervio (2008).

and implements the empirical strategy suggested by the model to interpret the observed differences. Section 6 concludes.

2 The Labor Supply of CEOs: Measurement

2.1 The CEO Time Use Survey

To measure CEOs' labor supply, we created a survey instrument that keeps track of the activities undertaken by executives on a daily basis.[4] We use this instrument to collect information for a sample of CEOs over one work week. While titles may differ across countries (e.g. Managing Director in the UK), we always interview the highest-ranking authority in charge of the organization who has executive powers and reports to the board of directors. For brevity we refer to them as CEOs in what follows.

The survey collects information on all the activities lasting 15 minutes or longer in the order they happened during the day, with their starting and ending time and other activity details. Our main measure of CEO labor supply is the sum of time devoted to work activities over the week. To compare our diary measure with the standard recall measure used in other time use surveys, we also asked CEOs to estimate the hours they worked during the same week. Figure A.1 in the Appendix shows a screenshot of the survey tool.[5]

The data was collected by a team of enumerators we hired for this purpose through daily phone calls with the Personal Assistant (PA) of the CEO, or with the CEO himself (43% of the cases), over a week randomly chosen by us. On day one of this week, the enumerator called in the morning and gathered detailed information on all the activities planned in the CEO diary for the day. The enumerator then called again in the evening to gather information on the actual activities undertaken by the CEO (including those that were not originally included in the planned agenda), and the activities planned for the following day. On subsequent days, the enumerator called in the evening, again to collect data on the actual activities undertaken during the day, and the planned schedule for the next day.[6] On the last day of the data collection, the analysts also interviewed the CEO to validate the activity data (if collected through his PA) and to collect information on the characteristics of the CEO and of the firm, including firm ownership and organizational structure.

[4] A similar version of the survey was first used in a small scale study of about 100 Italian CEOs. See Bandiera et al. (2012) for details.

[5] The survey tool can be found online at www.executivetimeuse.org.

[6] For 70% of the CEOs in our sample, the work week consisted of 5 days. The remaining 30% of the CEOs also reported to work during the weekend (21% for 6 days and 9% for 7 days). Analysts were instructed to call the CEO after the weekend to retrieve data on Saturdays and Sundays.

Sampling frame

The survey covers CEOs in six of the world's ten largest economies: Brazil, France, Germany, India, the United Kingdom and the United States. For comparability, we chose to focus on established market economies and opted for a balance between high and middle-low income countries. The sampling frame was drawn from ORBIS, an extensive commercial data set produced by the company Bureau Van Dijk that contains company accounts for more than 200 million companies around the world. To maintain comparability of performance data, we restricted the sample to manufacturing firms. We then selected firms with available sales and employment data.[7] This yielded a sample of 6,527 firms in 32 two-digits SIC industries that we randomly assigned to different analysts to call to seek the CEOs' participation.

We were able to interview 1,131 CEOs, a response rate of 17%. This figure is at the higher end of response rates for CEO surveys, which range between 9% and 16% (Graham et al. (2015)). Of the interviewed CEOs, 17 were later dropped from the sample because of low data quality (typically because the time use data covered less than 4 days of the week). Our final sample thus comprises of 1,114 CEOs, of which there are 282 in Brazil, 115 in France, 125 in Germany, 356 in India, 87 in the UK and 149 in the US.

The selection analysis in Table A.1 in the Appendix shows that respondents have on average lower log sales (coefficient -0.071, standard error 0.011). However, we do not find any significant selection effect on performance variables, such as sales over employees and return on capital employed (ROCE).

Measurement concerns

Two measurement concerns are of note. First, we are able to measure only the activities that the CEO is willing to report. The sign of the bias this creates is ambiguous. CEOs might indeed be prone to overestimate the hours they work, e.g. by coding time spent in personal activities as work. At the same time, we will not pick up activities that take place out of business hours unless they are recorded in the CEO diary. To the extent that the CEO labor supply data is estimated with error, this would create attenuation bias on the estimates.

Second, a week of detailed activity data might not be enough to capture typical CEO behavior. The allocation of time across activities might just be a reflection of high frequency shocks to the marginal cost or marginal product of time across CEOs. If so, the time use data would capture the relevance of these shocks, rather than explicit managerial choices. If this were true, however, we would expect little similarity in the way time is allocated within the week by the same CEO (i.e. we would not see any within week autocorrelation in CEO time use). In contrast, we find a high degree of autocorrelation in the average number of hours worked during the week by the CEOs.

[7] We went from a random sample of 11,500 firms to 6,527 eligible ones after screening for firms for which we were able to find CEO contact details and were still active. The sample construction is described in detail in the Appendix.

A simple regression of the number of log(hours worked) on day t on the same variable measured on day $t-1$ delivers a coefficient of .40, statistically significant at the 1% level. In addition, CEO fixed effects explain 25% of the variance observed in the daily time use data.

Finally, at the end of the survey week, we ask CEOs to rank whether the week could be considered "representative" of their usual work activity on a scale 1-10. Reassuringly, we observe substantial heterogeneity in hours worked even if we restrict the sample to the 63% of CEOs who score the survey week as highly representative (i.e. a score of 8, 9 or 10 out of 10). This is at odds with the hypothesis that all observed variation is due to transitory shocks rather than actual differences in behavior.

Ownership

In our sample, 57% of the firms are owned by a family, 23% by disperse shareholders, 9% by private individuals, and 7% by private equity.[8] Family CEOs are CEOs who belong to the family that owns the firm, and account for 41% of the sample. Of these, 329 (30% of the sample) are descendants of the original founders, and 126 (11%) are the founders themselves.[9] Detailed information of family ownership, which we were able to collect for a subsample of firms,[10] shows that the family firms in our sample tend to have a very concentrated ownership structure: families own on average 64% of the shares (66% at the median), and in 70% of the firms the family owns more than 50% of the shares.

Professional CEOs are CEOs who have no family bond with the owners of the firm. These account for 59% of the sample. Just over a quarter of them (16% of the sample) manage firms that are owned by a family. Later this will allow us to separate the effect of family ownership from the effect of family CEOs.[11] 43% of the firms are listed on the stock market.

2.2 CEOs at Work: Basic Summary Statistics

Figure 1 shows the distribution of hours worked during the week using the diary method, namely the sum of the duration of all the activities the CEO undertakes while at work. The average CEO in our sample spends 52 hours per week (10.4 hours per day) at work, while CEOs in the bottom

[8] The classification assigns ownership to the largest shareholder with at least 25.01% of the shares. We classify a firm as being owned by dispersed shareholders if no single entity, family or person owns at least 25.01% of the shares.

[9] In the robustness checks we investigate whether the main results vary between founders and descendants CEOs and find them to follow a very similar behavior.

[10] We gathered detailed ownership data for 324 of the total sample of 493 firms owned by a family or a founder. The 169 firms for which this data could not be retrieved are primarily (116) private firms located in Brazil, for which the detailed ownership information could not be found neither in Orbis nor via manual web searches. The remaining firms are located in France (3), Germany (5), India (38), UK (2) and US (5).

[11] The shares owned by the family are significantly higher (70% vs. 62%, difference significant at the 1% level) when the firm is family owned, but run by a professional CEO. Further details on our ownership measures are provided in the Appendix.

Figure 1: CEO weekly hours worked, diary measure

Notes: The graph shows the histogram of total weekly hours worked (built from actual diary data) by a sample of 1114 CEOs.

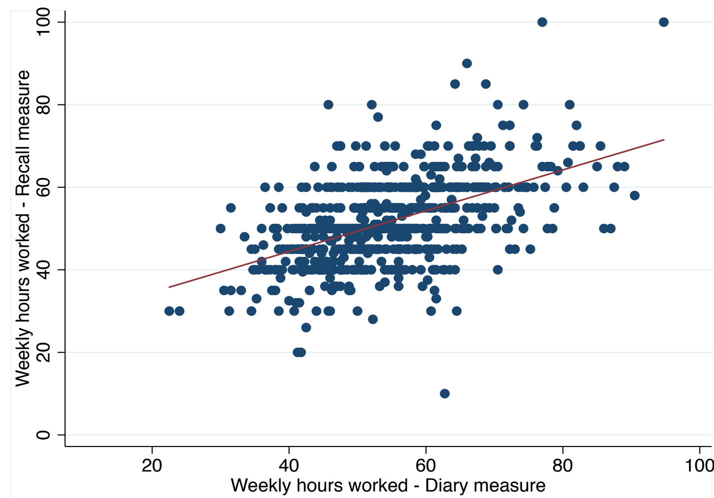
quartile work on average 44.2 hours per week and those in the top quartile work on average 58.5 hours per week.

Figure 2 compares the diary measure with a recall measure that we obtained by asking CEOs to estimate the number of hours worked at the end of the week.[12] Three points are of note. First, the distribution of the recall measure exhibits considerable bunching at round numbers, e.g. 26% of the sample CEOs report working 50 hours, while the diary measure shown in Figure 1 exhibits no bunching, i.e. no more than 1.5% of the sample take the same value. Second, the diary and the recall measures are positively correlated, but the correlation is well below 1–regressing the recall measure on the diary measure yields a coefficient of .50, significantly different from 1 with p-value equal to 0.00. Third, the recall measure is larger than the diary measure for half of the CEOs whose diary measure is below the mean, but only for 16% of the CEOs whose diary measure is above the mean. Thus, the noise in the recall measure is not orthogonal to the actual hours recorded in the diary–CEOs who work fewer hours are equally likely to over- or under estimate their hours worked while those who work longer hours tend to underestimate it. Taken together, these comparisons suggest that the bottom up estimate of CEO labor supply employed in the remainder of the paper is likely to provide more meaningful and objective information on CEO hours worked than more commonly used recall measures of labor supply.[13]

[12]The sample included in this analysis excludes India since we did not collect recall time use in the first wave of the survey.

[13]Robinson et al. (2011)discuss the impact of recollection biases in recall methods relative to the time-diary method. This notwithstanding, the diary method may still fail to capture some activities or still allow respondents to overestimate the time they devote to other activities, so that the hours of work recorded in our survey should be seen as

Figure 2: CEO weekly hours worked, diary and recall measure



Notes: The graph shows the linear regression of total weekly hours worked (CEO estimates recorded at the end of the data collection week) and actual hours worked (built from diary data) for a sample of 758 CEOs (all CEOs in sample excluding India, where the recall question was not asked).

Notes: The graph shows the linear regression of total weekly hours worked (CEO estimates recorded at the end of the data collection week) and actual hours worked (built from diary data) for a sample of 758 CEOs (all CEOs in sample excluding India, where the recall question was not asked).

Table A.3 shows that total weekly hours worked are similar across countries and above 50 hours per week on average (or above 9.8 hours a day) across all countries except India, where the average number of hours worked across all CEOs is significantly lower (46 weekly hours, or 8.8 hours a day). Overall, country fixed effects are jointly significant at the 1% level and account for about 14% of the variation in total hours worked observed in the data. In contrast, industry fixed effects–while being jointly significant at the 1% level–account for only 3% of the overall cross sectional variation in total hours worked. In the main analysis we rely primarily on within country, within industry comparisons of CEO hours worked across different governance types.

3 The Labor Supply of CEOs: Family vs. Professional CEOs

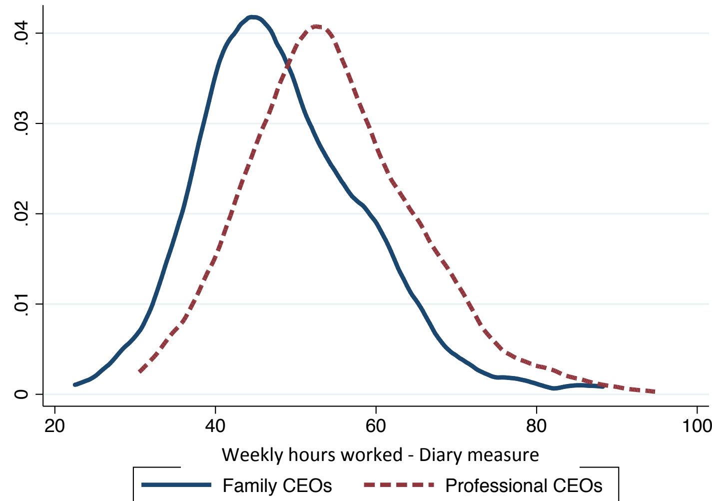
3.1 Differences in Hours Worked

Figure 3 plots the distribution of weekly hours worked by family and professional CEOs as they appear in the raw data. While there is a wide heterogeneity in hours worked across both types of CEOs, the distribution of hours worked by family CEOs is entirely shifted to the left relative to professional CEOs. This is the main stylized fact documented in this paper.

Table 1 provides some additional summary statistics to better qualify the nature of this difference. The first and second rows report the recall and diary measures of hours worked described

a proxy of actual work hours. See Aguiar et al. (2012) for a comprehensive review of the growing literature in the economics of time use.

Figure 3: CEO hours worked: differences between family and professional CEOs in the raw data



Notes: The graph shows the kernel distribution of total weekly hours worked (built from actual diary data) by a sample of 1114 CEOs, of which 458 classified as "family CEOs", and 656 classified as "professional CEOs".

Notes: The graph shows the kernel distribution of total weekly hours worked (built from actual diary data) by a sample of 1114 CEOs, of which 458 classified as "family CEOs", and 656 classified as "professional CEOs".

earlier. By both measures family CEOs work fewer hours, but importantly the difference is much larger (6.2 vs 3.6 hours) when we use the diary measure, as family CEOs tend to overestimate their time at work while professional CEOs underestimate it.[14]

The difference remains stable (6.8 hours) when we only count work activities (that is dropping travel time and personal time) that last longer than 15 minutes. The difference between governance types is due to two factors. Family CEOs start working later in the morning–at 9.16AM vs. 8.31AM for professional managers–and devote a larger share of time to personal activities during business hours (12.3% vs 8.6%).

3.2 Hours Worked and Firm Performance

The data shows a large statistically significant differences in hours worked across CEOs, but are these differences interesting from an economic perspective? To provide some evidence on this point, we examine three related issues. First, are there are performance differences between family and professional CEOs? Second, do CEO hours worked correlate with firm performance? And, finally, to what extent do differences in CEO hours worked account for the performance gap between family and professional CEOs?

To examine these questions, we match the CEO survey data with firm-level accounting data

[14]Note that the recall measure is more prone to be biased by systematic misreporting (Robinson et al. (2011)). Therefore, this finding allays the possible concern that the difference in hours worked between family and professional CEOs may be driven by professional CEOs intentionally overstating their effort at work.

Table 1: Differences in time use between family and professional CEOs

	(1)	(2)	(3)	(4)

Notes: The table shows summary statistics (means, standard deviation in parentheses in columns 1-3, differences and t-statistic in parentheses in column 4) of time use for the sample CEOs. Family CEOs are those who own the firm or belong to the family that owns the firm. All variables collected in the CEO time use survey.

Notes: The table shows summary statistics (means, standard deviation in parentheses in columns 1-3, differences and t-statistic in parentheses in column 4) of CEO time use, CEO characteristics, firm and industry level data for the sample CEOs. Family CEOs are those who own the firm or belong to the family that owns the firm. All variables in Panel A, B and C collected in the CEO time use survey. Import penetration = ln(import/production) in the firm ISIC REV3 industry, computed by averaging OECD STAN data relative to the 2006–2008 time period (last available year for all countries) across France, Germany, US and UK at the industry level. Lerner index of competition = (1-profit/sales) in the firm 3 digit SIC industry computed , as in Aghion et al. (2005), by averaging firm level data in ORBIS relative to the 2008-2012 time period across Brazil, France, Germany, India, US and UK at the industry level.

extracted from the Bureau Van Dijk's ORBIS database. This database provides digitized and comparable company accounts covering very large samples of private and publicly listed firms.[15] We start by considering firm productivity as a proxy for firm performance (Syverson (2011)), and estimate by OLS a basic production function of the form:

$$y_{it} = \alpha^F Fam + \alpha^l l_{it} + \alpha^k k_{it} + \alpha^h h_i + \gamma' Z_{it} + u_{it} \quad (1)$$

where y_{it} are sales, l_{it} is labor, k_{it} capital of firm i at time t and lower case letters denote natural logarithms. CEO log hours worked are denoted by h_i. We restrict the analysis to the years in which the manager we interviewed had the role of CEO, and for each firm we keep the three most recent years prior to the survey year to avoid selection on CEOs with longer tenure. We include year and country by industry (at the two digit SIC level) dummies throughout, as well as a set of interview noise controls to control for measurement error in the time use variables,[16] and cluster the standard errors by firm throughout the table.

The results of this analysis are shown in Table 2. Column 1 shows that firms run by family CEOs in our sample are on average less productive than those run by professional CEOs. The difference in log sales controlling for employment and capital between firms run by family CEOs and those run by professional managers is -0.190 log points (standard error 0.071), which translates in a 20% productivity gap with firms run by professional CEOs.[17] The coefficient on capital and employment are both precisely estimated and within the expected range of magnitude (0.336, standard error 0.031 for capital and 0.555, standard error 0.041 for labor).

Column 2 shows that hours worked by the CEO are correlated with performance. The association between hours worked and productivity is positive and precisely estimated: a 10% change in weekly hours worked is associated with a 3.3% increase in labor productivity.[18] Furthermore,

[15]See the Appendix for details.

[16]The noise controls include: a dummy to denote if the time use data was recorded by the PA; 55 interviewer dummies; a dummy to denote CEOs who formally report to an executive Chairman; 29 interview week dummy; a self reported score given by the CEO to rank the representativeness of the week and a dummy to denote weeks with a national or religious holiday. As expected, these controls improve the precision of the estimates of the coefficient on CEO hours worked, but the results are robust to their exclusion. To the extent that our measures reflect time use shocks that hit in that particular week or biases in reporting time use that are orthogonal to yearly firm outcomes, the estimated coefficient on CEO hours worked will be biased towards zero.

[17]This result is in line with previous research on family run firms by Morck et al. (1988), Smith and Amoako-Adu (1999), Pérez-González (2006), and Bennedsen et al. (2007). Anderson and Reeb (2003), in contrast, report that public firms with a large block held by an individual or family on average are assigned higher values by public shareholders. However, it is worth noting that the positive effect of family ownership documented in Anderson and Reeb (2003) tapers off from shares of family ownership of 30% and above, and turns negative at about 60%. Since, as discussed earlier, the share of family ownership in the family firms in our sample is very high (66% at the median), the two sets of results are in fact consistent with each other. The results differ to some extent from Villalonga and Amit (2006a), in that we find a negative correlation between firm performance and family control even when the CEO is a founder (in Villalonga and Amit (2006a), the negative effect of family CEOs emerged only for second generation CEOs and onwards). A possible reason for this discrepancy stands in the fact that our sample includes a large fraction of private firms in six countries, while Villalonga and Amit (2006a) focus on listed US firms only.

[18]For comparison, a one standard deviation change in capital would be associated with a 46% increase in productivity, while a standard deviation change in log CEO hours worked would result in an increase by 8%.

the inclusion of CEO hours worked reduces the coefficient on the family CEO dummy by 18%, suggesting that the difference in hours worked account for almost a fifth of the productivity gap.

We repeat the exercise using the Olley and Pakes (1996) estimator of productivity in columns 3 and 4, finding consistent results: firms run by family CEO are on average less productive than firms run by professional CEO, differences in CEO hours worked are positively associated with productivity, and account for about 20% of the productivity gap between family and professional CEO firms. Columns 5 and 6 reveal a similar pattern when we use profits per employee as a metric of firm performance, and Tobin's Q in columns 7 and 8, which is available for the subset of listed firms in the sample. In Appendix Table A.4 we report similar results using inputs rather than outputs as dependent variables (log investments and log average wages).

Overall, these findings show the presence of a significant relationship between the CEO owning, or being part of the family that owns the firm, working fewer hours, and worse firm performance. The evidence of a positive correlation between CEO effort and firm performance is–to the best of our knowledge–novel.[19] One possible interpretation of this finding is that CEO effort is a relevant managerial input in production, and that differences in hours worked between family and professional CEOs may be one of the causal factors behind the performance differences between family and professional CEO firms. Unfortunately, however, the direction of causality behind these relationships cannot be pinned down using cross-sectional data. For example, CEO hours worked may have no direct effect of firm performance, but more productive firms might demand more CEO effort, or unobservably more productive firms may be more likely to hire CEOs who happen to work longer hours.[20]

[19] Pencavel (2014) examines the correlation between hours of work and productivity among munition workers.

[20] Note that unobserved heterogeneity across firms may also affect the estimation of the coefficient α^F in Equation 1 (i.e., the coefficient on the family CEO dummy). Bennedsen et al. (2007), for example, show that correcting for the endogeneity and omitted variable concerns in the choice of a family CEO leads to a large reduction in the α^F coefficient, i.e. the appointment of a family CEO is more likely when unobserved firm performance is expected to improve. Extrapolating their results to our sample, this would imply that the OLS coefficient on α^F shown in Table 2 may be upward biased. While this hypothesis is certainly plausible, three pieces of evidence alleviate the endogeneity concerns about α^F in our sample. First, the magnitude of the productivity gap between family and professional CEOs estimated with OLS is very similar to the one obtained using the Olley Pakes estimator of productivity, which takes into consideration endogeneity biases in the production function estimation. Second, we are able to observe firm performance before the CEO was appointed (363 firms) and, in this subsample, we do not find evidence of differential pre-appointment trends in performance between family and professional CEOs, even when focusing on professional CEOs replacing a family CEO (see Appendix Table A.5). Third, if unobserved productivity were positively correlated with CEO hours, including it as an additional regressor in Equation 1 would lead to a further decrease in the α^F coefficient, which is opposite to what we observe in Table 2. On a related note, we also considered whether the reduction of the coefficient α^F when CEO hours worked are included in the production function could be driven by systematic differences in reporting biases between family and professional CEOs. Two pieces of evidence, however, suggest that mismeasurement does not systematically vary across governance types. First, the correlation between actual and self-reported hours is not statistically different across governance types (the coefficient on the regression of log perceived hours worked on log actual hours worked is 0.54 (se 0.07) for family CEOs and 0.49 (se 0.04) for professional CEOs, and the difference is not significant). Second, we examined whether family and professional CEOs varied in terms of the representativeness of the week chosen for the data collection using a self-reported measure that we collect from the CEO when reviewing the data. This variable is also not statistically different across family and professional CEOs.

Notes: *significant at 10%; ** significant at 5%; *** significant at 1%. All columns estimated by OLS (standard errors under coefficient clustered by firm). The variable "CEO Hours Worked" is the log of the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during the survey week. The dependent variable in columns 1 and 2 is log sales; in columns 3 and 4, the Olley Pakes (1996) estimator of productivity; in columns 5 and 6, profits per employee; in columns 7 and 8, Tobin's Q. Accounting data run between 2007 and 2013. Each column includes a full set of country by 2 digits SIC and year dummies. We include only years in which the CEO was in office in all columns, and allow for a maximum of three years of accounts for each firm (3 most recent years with non missing data in ORBIS). All columns include the following noise controls include: a dummy to denote case in which the time use data was recorded by the CEO's Personal Assistant; 55 interviewer dummies; a dummy to denote CEOs who formally report to an executive Chairman; 29 interview week dummy; a self reported score given by the CEO to rank the representativeness of the week and a dummy to denote weeks with a national or religious holiday.

In what follows we abstract completely from the challenge of estimating the causal effect of CEO effort on firm performance. Instead, we focus on a more specific question, which is: taking it as a given that the variation in CEO effort will to some extent reflect firm specific characteristics, including differences in firm performance, is there any role left for individual CEO preferences in explaining the difference in hours worked across CEOs? In particular, is it possible that family CEOs may have a different preference for leisure relative to professional CEOs? In the next section we present a simple model to guide the empirical investigation of these questions.

4 A Simple Model of CEO Labor Supply

The model contains two main elements: a production function that depends on CEO work time, as mediated by a) the characteristics of the CEO and the firm and; b) CEO preferences. Time allocated to an activity is taken as a proxy for CEO attention which, as in Geanakoplos and Milgrom (1991), is akin to a factor of production and matches the empirical model in equation (1).

Starting with technology, the performance of a firm is given by:

$$y_{gs} = \overline{y}_{gs} + (a_g + b_s)\, h_{gs} - \frac{1}{2} h_{gs}^2 \tag{2}$$

where $g \in \{F, P\}$ indicate the type of CEO–family or professional–and $s \in \{L, H\}$ denotes a binary state of the world, to be discussed later. Firm performance–y_{gs}–depends on the number of hours that the CEO works, h_{gs}. The marginal effect of a CEO hour depends on his type (a_g), and the state of the world (b_s). The negative quadratic term captures the idea that the marginal return of CEO time is decreasing. Firm performance may also depend directly on the CEO type and on the state of the world through $\overline{y}_{gs}$.

Note that the only restriction that our formulation imposes, by having additive a_g and b_s rather than a generic a_{gs}, is that the identity of the CEO does not interact directly with the state of the world in determining the marginal effect of CEO time on performance. In the model, we do not take a stand on whether performance is innately higher or lower in firms run by family CEOs or professional CEOs: $\overline{y}_{Fs}$ can be greater or smaller than $\overline{y}_{Ps}$. We also remain agnostic as to whether the return to CEO time is higher or lower for family compared to professional CEOs: a_F can be greater or smaller than a_P. For example, the marginal productivity of a professional CEO might be different from that of a family CEO because the family CEO can delegate more easily to other family members who are more likely to work for the firm.

CEO utility depends on the performance of the firm and on the cost of spending time at work:

$$u_{gs} = c_g y - d_s h_{gs},$$

where c_g represents the relative weight of firm performance and work hours in the preference of a CEO of type g;[21] and d_s captures the possibility that the cost of effort, or the opportunity cost of

[21] Differences in c_g may be innate to the CEO or compensation related. For example, different governance types

leisure, depends on the state of the world common across all CEOs.[22]

In this simple set-up, given technology and preferences, the number of hours maximizing CEO payoff is derived as:

$$h^*_{gs} = a_g + b_s - \frac{d_s}{c_g} \tag{3}$$

Equation (3) illustrates the primary identification challenge we face in a cross sectional setting, and that were briefly discussed in Section 3.2. Namely, differences between the hours worked by family and professional CEOs can be due to either differences in firm or CEO characteristics that vary across governance types and determine the marginal product of CEO's hours (a_g) or by differences in the relative weight the CEO assigns to firm performance (c_g).

The model, however, also provides a key insight that can be used to identify at least the sign of the difference between c_F and c_P. More specifically, factors that affect the opportunity cost of leisure/marginal cost of effort d_s to the same extent for both CEO types can be used to identify differences in managerial preferences (i.e. whether c_g effectively differs across CEOs). To see this, suppose that the cost of effort is higher (or the opportunity cost of leisure lower) in state H than in state L ($d_H > d_L$). In this case, we can show that, even if a change in the state of the world may affect the marginal productivity of CEO work through b_s, the sign of the difference-in-differences depends on the preference parameter c_g only:

Proposition 1. *The difference in difference in hours worked over CEO type and state of the world has the same sign as the difference in the preference parameter of family CEOs and professional CEOs. Formally, if* $d_H > d_L$ then $h^*_{PH} - h^*_{FH} > h^*_{PL} - h^*_{FL}$ *if and only if* $c_P > c_F$.[23]

Intuitively, if preferences are the same across CEOs, and the difference between family and professional CEOs is solely driven by the marginal product of CEO time a_g, an increase in the marginal cost of effort d_s that affects both types equally should make both types reduce hours worked *to the same extent*, leaving their difference constant. By the same logic, if the difference in hours worked across CEOs instead increases with d_s, this is consistent with the idea that family CEOs have a stronger preference for leisure relative to firm performance.

We take this approach to the data in the next section.

may be associated with differences in performance-related pay.

[22]Note that the utility function can be rewritten as $u_{gs} = \frac{c_g}{d_s} y - h_{gs}$. Therefore, the parameter d_s captures differences in the trade-off between firm performance and leisure.

[23]Proof. Given the optimal h and the assumption that $d_H > d_L$,

$$\begin{aligned} sign\left[h^*_{FL} - h^*_{FH} - (h^*_{NL} - h^*_{NH})\right] &= sign\left[\tfrac{d_H}{c_F} - \tfrac{d_L}{c_F} - \tfrac{d_H}{c_N} + \tfrac{d_L}{c_N}\right] \\ &= sign\left[-\left(\tfrac{1}{c_N} - \tfrac{1}{c_F}\right)(d_H - d_L)\right] = sign\left[c_N - c_F\right] \end{aligned}$$

5 Why do Family CEOs Work Less than Professional Managers?

5.1 The Role of Firm, CEO and Industry Characteristics

In line with earlier work (e.g. Pérez-González (2006)), family CEOs are different in other dimensions besides how long they work. This is shown in Table 3, Panels A, B and C. Panel A shows that family and professional CEOs have similar demographics: the average CEO is 51 years old and 96% of CEOs are men. However, the share of family CEOs with a college degree and/or an MBA is significantly lower relative to professional managers (90% vs. 94% for a college degree, p-value <.1, and 43% vs 63% for an MBA degree, p-value<.01). Family CEOs are also less likely to have worked abroad (39% vs. 54% , p-value<.01) and more likely to have longer tenure both as CEOs (16 vs 7 years, p-value<.01) and in other positions with the same firm (23 vs 13 years, p-value<.01).

Panel B shows that the average firm has 1,571 employees and that family CEOs manage smaller firms (1,037 vs 1,945 employees, p-value>.1). 24% of the sample firms are part of foreign multinationals, and these are less likely to be managed by family CEOs (19% vs 28%, p-value<.01). The organization of the firm also differs: family CEOs have fewer direct reports (7.4 vs 8, p-value<.05) and are also less likely to have a COO (18% vs 31%, p-value<.01), while they are much more likely to have their offsprings in executive positions within the firm (.24 sons and .10 daughters vs. .005 and .006, p-values<.01).

Finally, Panel C describes the external environment in which these firms operate. 57% of the sample firms are located in emerging economies (India or Brazil), with this number being higher for firms led by family CEOs (78% vs 43%, p-value<.01). The sample firms are distributed across 32 different two digits SIC sectors, the largest of which, SIC 28 (Chemicals and Allied Products), accounts for 13% of the firms. The distribution of family and professional CEOs are generally balanced across sectors. We reject the null that the sector dummies do not predict CEO type only for 4 out of the 32 sectors, three of which account for less than 2% of the sample each. Family and professional CEOs also face a similar level of product market competition, as measured by the Lerner Index, which is defined as (1-profit/sales) calculated as the average across the entire population of firms in Orbis in the sample countries for the 5 years preceding the data collection, and is specific to the firm three digit industry (Aghion et al. (2005)). We obtain similar results when we use the degree of import penetration as a proxy for product market competition, measured as the share of total imports relative to domestic production in the industry in which the firm operates, also aggregated up at the industry level.[24]

To assess the relevance of these factors in accounting for the gap in hours worked between family and professional CEOs, we estimate an empirical version of equation (3), i.e.:

$$h_{ijc} = \alpha^F Fam_i + C_i\beta + F_i\gamma + \delta_{jc} + \varepsilon_{ijc} \tag{4}$$

[24]See Section A.3 in the Appendix for more information on the construction of the Lerner and the import penetration variables.

Notes: The table shows summary statistics (means, standard deviation in parentheses in columns 1-3; differences and t-statistic in parentheses in column 4) of CEO characteristics, firm and industry level data for the sample CEOs. Family CEOs are those who own the firm or belong to the family that owns the firm. All variables in Panel A and B collected in the CEO time use survey. Import penetration = ln(import/production) in the firm ISIC REV3 industry, computed by averaging OECD STAN data relative to the 2006–2008 time period (last available year for all countries) across France, Germany, US and UK at the industry level. Lerner index of competition = (1-profit/sales) in the firm 3 digit SIC industry computed, as in Aghion et al. (2005), by averaging firm level data in ORBIS relative to the 2008-2012 time period across Brazil, France, Germany, India, US and UK at the industry level.

Where h_{ijc} is the log of total weekly hours worked by CEO i in industry j in country c, Fam_i equals 1 if firm i is owned by a family and the CEO belongs to the family, while $Fam_i = 0$ if firm i is led by a professional CEO regardless of ownership status, C, F are vectors of CEO and firm characteristics, δ_{jc} are industry by country fixed effects. We examine the extent to which the magnitude and the significance of the coefficient α^F is affected by the inclusion of these controls (robust standard errors are reported in parenthesis under the coefficients).

The results are shown in Table 4. Column 1 shows that the unconditional difference between the hours worked of family and professional CEOs is 16% (0.18 log points). Column 2 shows that one third of this difference is due to differences across countries, namely CEOs in emerging economies record fewer hours and family CEOs are more likely to be located there (more details on country differences are shown in Table A.3). Adding country by 2 digit SIC industry fixed effects reduces the difference from 16% to 11%.

Column 3 shows that older CEOs work fewer hours (coefficient on log CEO age is -0.165, significant at the 1% level). While proxies for CEO skills (college degree dummy, MBA dummy, and an indicator to denote CEOs with work experience abroad) are all positively but only weakly correlated with hours worked. The inclusion of these additional controls leaves the coefficient on the family CEO dummy unchanged.

In Column 4 we examine the association between industry and firm characteristics and CEO hours worked by including a set of variables likely to affect the magnitude and the complexity of CEO workload such as firm size (in terms of employees), firm age and a dummy denoting firms that are either domestic or foreign multinationals to capture the possibility of extended working hours due to the necessity of managing across different time zones. Among these variables, only firm size is positively and significantly correlated with CEO hours worked. A 10% increase in firm size is associated with a 0.25% increase in CEO hours worked.[25] Overall, however, industry fixed effects, CEO and firm characteristics explain a small portion of the difference in hours worked between family and professional CEOs, which remains unchanged in magnitude even when these additional controls are included.

Column 5 controls for firm organizational features, i.e. the number of CEO direct reports, a dummy to denote the presence of a COO, and the number of sons and/or daughters employed in senior managerial positions. These variables are of particular interest for our purposes, since they differ systematically between firms managed by family and professional CEOs–as shown in Table 3–and may at the same time significantly shape overall the demands on CEO time.[26] Differences in

[25]For a subsample of firms, we were able to build alternative measures of firm size based on accounting data using information of firm level sales. We also investigated whether the differences in hours worked could be accounted for different growth rates–rather than levels–of sales. We found similar results, namely that CEO hours worked are higher in larger firms, but that does not account for the differences between family and professional CEOs. CEO hours worked are positively but not significantly correlated with the growth rate of firm sales, and the inclusion of the variable does not affect the family CEO dummy (see Appendix Table A.7 for details).

[26]For example, the presence of other family members in top managerial positions may facilitate the distribution of

Notes: *significant at 10%; ** significant at 5%; *** significant at 1%. All columns estimated by OLS (robust standard errors in parenthesis). The variable "CEO Hours Worked" is the log of the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during the survey week. Family CEO=1 for those who own the firm or belong to the family that owns the firm, and 0 otherwise. Family Ownership, External CEO=1 for professional CEOs working in firms owned by a family, and 0 otherwise. Industry dummies are 33 two digits SIC codes. Noise controls include: a dummy to denote if the time use data was recorded by the PA; 55 interviewer dummies; a dummy to denote CEOs who formally report to an executive Chairman; 29 interview week dummy; a self reported score given by the CEO to rank the representativeness of the week and a dummy to denote weeks with a national or religious holiday.

organizational structure are indeed correlated with CEO hours worked. Namely, CEOs who have a larger number of direct reports work longer hours, while those whose sons hold senior management positions in the firm work fewer hours. Differences in organizational structure reduce the coefficient on family CEOs by 2 percentage points, but this remains economically and statistically significant.

Column 6 further probes the result to the inclusion of the set of interview noise controls included in the production function results in Table 2 to proxy for systematic differences in measurement error across CEO types. Reassuringly, the inclusion of these controls leaves the magnitude and the significance of the family CEO dummy unchanged. We also note that there is no correlation between the identity of the survey respondent (the PA or the CEO himself) and hours worked, which allays concerns that PAs have more limited information or that CEOs who choose to report their own time use overstate hours worked.[27]

Since 16% of the sample firms are owned by a family and managed by a professional CEO we can separately identify the effect of family CEOs from the effect of family ownership. Column 7 shows that professional CEOs working in firms owned by a founder or a family are statistically indistinguishable from other professional CEOs. This finding is important, as it suggests that the differences in hours worked between family and professional CEOs are not due to factors related to family ownership *per-se*, but are tightly linked to the presence of a family affiliated manager.

Robustness Checks

Table A.6 in the Appendix shows a battery of robustness checks, including expressing CEO hours worked in levels, using a negative binomial regressions to take into account the count nature of the hours data, estimating the regression separately for developing (Brazil and India) and developed (France, Germany, UK and US) economies, and the first wave of the survey (which focused on India exclusively) and the second wave of the survey (in which all the other countries were covered). The magnitude and significance of the family CEO dummy are remarkable stable across methods and samples.

Finally, in Appendix Tables A.8 and A.9 we explore whether the results vary when we consider first and second generation family CEOs separately, i.e. founders separately from descendants. Table A.8 shows that, unconditionally, founders work 1.3 fewer hours per week relative to professional CEOs, but they are also are older, less educated, have longer tenure and are mostly located

CEO workload across a team of trusted managers (Bloom et al. (2013)). These organizational decisions may clearly also be endogenous to CEO effort.

[27]The coefficient remains stable at .088 even if we include all the other noise controls but we remove the variable capturing the identity of the respondent. To address measurement issue concerns, we also replicated the analysis using a recall measure of hours worked, rather than the actual diary based measure. This is because, with significant reporting biases, we would expect the difference in hours worked between family and professional CEOs to be larger when using the recall measure, which is easier to manipulate. In contrast with this hypothesis, we find that the estimated difference in hours worked between family and professional CEOs is smaller when we use the recall measure. This is consistent with the fact that–as shown in Table 1–family CEOs are more likely to overstate hours worked relative to professional CEOs.

in emerging economies. Once all observable characteristics are controlled for, Columns 5 and 6 in Table A.9 show that both founder and descendant CEOs affiliated with the owning family work 9% fewer hours than professional CEOs.[28]

Summary

Taken together, the evidence presented so far does not support the idea that the firm or managerial characteristics affecting the marginal product of CEO time–a_g in the terminology of the model–are the sole drivers of the observed differences in hours worked across CEOs. First, the correlation between any of these variables and hours worked is an order of magnitude smaller than the effect of CEO type. Second, differences in CEO and firm observable characteristics, including family ownership, explain only about half of the difference in total hours between family and professional CEOs.[29]

The remaining gap in hours worked might be due to other unobservable differences that are specific to family firms, but only when managed by family CEOs, and/or to differences in the preferences of the CEOs. We attempt to disentangle these two potential sources of variation in Section 5.2 below.

5.2 CEO Preferences

Heterogeneity across Firms

Proposition 1 of the model suggests that differences in managerial preferences across CEOs should result in differential responses with respect to variations in the opportunity cost of leisure common across across all CEOs. We investigate this idea by examining two factors that should affect the CEO opportunity cost of leisure: firm size and the level of competition the firm is exposed to.

In both cases, the intuition is straightforward. The opportunity cost of leisure is likely to be higher in larger firms because the CEO controls a larger volume of activity. Therefore, the marginal hour of leisure deprives more people of the input of the CEO, and each decision not taken during that hour has larger monetary value. This is akin to the "scale of operations" effect (Mayer (1960)). Symmetrically, the opportunity cost of leisure is likely to be higher in more competitive settings, because the baseline probability of survival is lower, and CEO effort is more likely to be essential to keep the firm in business. The marginal hour of leisure can make the difference between firm death and survival in competitive industries while its consequences are less dire for firms that are sheltered from competition.

[28]While it is important to notice that the founders managed firms in our sample are not start-ups (the average founder has been managing his firm for 22 years), the finding that founder and descendant CEOs behave similarly is in line with recent findings that both adopt worse managerial practices (Bloom and Van Reenen (2007)) and that they share a similar business philosophy and firm governance (Mullins and Schoar (2013)).

[29]To see this, compare the coefficient on the family CEO dummy in Table 4, Column 1 with the one in Column 7.

Table 5 reports the estimates of

$$h_{ijc} = \alpha^F Fam_i + \beta Fam_i * X_{ij} + \gamma X_{ij} + C_i\varphi + F_i\phi + \delta_{jc} + \varepsilon_{ijc} \tag{5}$$

where X_{ij} is a measure of firm i size, or a measure of competition in industry j, and all other variables are as defined above. Proposition 1 makes clear that, under the assumption that the opportunity cost of leisure is higher in larger firms and in more competitive industries, the difference in difference parameter β has the same sign as the difference in preferences between professional and family CEOs. Namely, $\beta>0$ implies that, compared to family CEOs, professional CEOs put more weight on firm performance relative to leisure.

In Table 5 we use two measures of firm size, number of employees and revenues, and two measures of competition, the Lerner index and import penetration, both defined at the industry (SIC 3 and ISIC Rev1, respectively) level. The estimates in columns 1 to 4 reveal a consistent picture: when the opportunity cost of leisure is higher, the difference in hours worked between family and professional CEOs is smaller. The estimates of β are positive and statistically different from zero for all four measures, and the magnitudes are economically meaningful. The difference between family and professional CEOs is 12% (11%) in firms at the 10th percentile of the distribution of log employment (log sales) but only 4% (5%) in firms at the 90th percentile of the same distribution. Thus, family CEOs in large firms work almost as much as their professional counterparts, while those in small firms work significantly less. Likewise, the difference between family and professional CEOs is 10% in low competition industries at the 10th percentile of the Lerner (import penetration) index but only 5% in high competition industries at the 90th percentile. These magnitudes are almost identical when we consider import penetration as an alternative proxy for competition.

In light of Proposition 1, the estimates with respect to size and competition are consistent with a scenario in which family CEOs put lower weight on firm performance relative to leisure, that is $c_P > c_F$. However, an observationally equivalent explanation is that there is a distribution of preferences for leisure among family CEOs, and variation in the opportunity cost of leisure at the firm or industry level determines sorting, so that leisure-loving family CEOs are only found in small firms and low-competition industries. In this case, leisure-loving family CEOs drop out rather than working longer hours, although note that differences in preferences still explain differences in hours worked. The next subsection exploits variation in the cost of effort across days to shed light on whether family and professional CEOs adjust their hours differently in response to exogenous shocks.

Heterogeneity across Days

For the two largest of our sample countries–India and Brazil– we are able to exploit shocks affecting the cost of CEO effort *during* our sample week. In these two countries, the data collection period coincided with intense rainfall days (especially in India, in which it overlapped with the onset and

Notes: *significant at 10%; ** significant at 5%; *** significant at 1%. All columns estimated by OLS. In all columns robust standard errors under coefficient clustered by 3 digits SIC codes. The variable "CEO Hours Worked" is the log of the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during the survey week. Family CEO=1 for those who own the firm or belong to the family that owns the firm, and 0 otherwise. All columns include country and industry dummis, as well as CEOand firm characteristics, and noise controls. Industry dummies are 33 two digits SIC codes. CEO characteristics are a dummy to denote CEOs holding a managerial or board position in another firm, the log of CEO age, the log of one plus number of years CEO has been employed in the firm, a dummy to denote CEOs holding a college degree, a dummy to denote CEOs holding an MBA or equivalent degree, a dummy to denote CEO that have worked or studied abroad. Firm characteristics are the log of one plus firm age, a dummy to denote foreign or domestic multinationals, the number of people reporting directly to the CEO, a dummy to denote whether the firm employs a COO, the number of CEO's sons and daughters holding a managerial position in the same firm. Noise controls include: a dummy to denote cases in which the time use data was recorded by the CEO's Personal Assistant, 55 interviewer dummies, a dummy to denote CEOs who formally report to an executive Chairman, 29 interview week dummy; a self reported score given by the CEO to rank the representativeness of the week and a dummy to denote weeks with a national or religious holiday. Import penetration = Log(import/production) in the firm ISIC REV3 industry, computed by averaging OECD STAN data relative to the 2006–2008 time period (last available year for all countries) across France, Germany, US and UK at the industry level. Lerner index of competition = (1-profit/sales) in the firm 3 digit SIC industry computed, as in Aghion et al. (2005), by averaging firm level data in ORBIS relative to the 2008-2012 time period across Brazil, France, Germany, India, US and UK at the industry level.

Notes: *significant at 10%; ** significant at 5%; *** significant at 1%. All columns estimated by OLS. The variable "CEO Hours Worked" is the log of the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during the survey week. Family CEO=1 for those who own the firm or belong to the family that owns the firm, and 0 otherwise. Lerner index of competition = (1-profit/sales) in the firm three digits SIC industry computed, as in Aghion et al. (2005), by averaging firm level data in ORBIS relative to the 2008-2012 time period across Brazil, France, Germany, India, US and UK at the industry level. Import penetration = ln(import/production) in the firm ISIC REV3 industry, computed by averaging OECD STAN data relative to the 2006–2008 time period (last available year for all countries) across France, Germany, US and UK at the industry level (the linear term is omitted as is perfectly collinear with two digits SIC dummies, also included as controls). All columns include country and industry dummies, as well as CEO and firm characteristics, and noise controls. Industry dummies are 33 two digits SIC codes. CEO characteristics are a dummy to denote CEOs holding a managerial or board position in another firm, the log of CEO age, the log of one plus number of years CEO has been employed in the firm, a dummy to denote CEOs holding a college degree, a dummy to denote CEOs holding an MBA or equivalent degree, a dummy to denote CEO that have worked or studied abroad. Firm characteristics are the log of one plus firm age, a dummy to denote foreign or domestic multinationals, the number of people reporting directly to the CEO, a dummy to denote whether the firm employs a COO, the number of CEO's sons and daughters holding a managerial position in the same firm. Noise controls include: a dummy to denote cases in which the time use data was recorded by the CEO's Personal Assistant; 55 interviewer dummies; a dummy to denote CEOs who formally report to an executive Chairman; 29 interview week dummy; a self reported score given by the CEO to rank the representativeness of the week and a dummy to denote weeks with a national or religious holiday. Robust standard errors in columns 1 and 2. Standard errors are clustered at the three digit SIC level in column 3, and at the ISIC REV3 industry level in column 4.

early development of the monsoon rainfall season) and with popular sports tournaments (cricket in India and soccer in Brazil). These events affect the cost of effort on some days but not on others and, crucially, affect both family and non family CEOs in the sample. These features of the shocks provide enough variation to identify whether CEOs display a differential reaction to the same exogenous shocks.

Extreme rainfall disrupts local transportation in urban areas (where most of the CEOs in our sample are located), adding delays and inconveniences that increase the cost of effort. We obtain rainfall data for all the major weather stations in India and Brazil for the period in which the data was collected, as well as for previous months. We classify a day as having extreme rain if its deviation from the driest month in the year preceding the survey (May 2011 in India and July 2012 in Brazil) falls in the upper third of the station level distribution of the same variable. By this measure, 403 CEOs out of 597 CEOs (or 67% of the sample) experience extreme rain at least once during the survey week.[30]

The second quasi-natural experiment we exploit is the happening of important sport matches, cricket in India and soccer in Brazil. These sports are extremely popular in these countries, and the cost of effort is likely to be higher during a match for an average individual, including CEOs. For this test, we take advantage of the fact that our data collection partially overlapped with key events: the playoffs, semifinals and finals of a major cricket tournament, the Indian Premier League (IPL), in India; and popular soccer matches played by top teams in the 2013 State Football League in Brazil.[31] For both countries, we collect data on the timing of these matches and classify a day to have a sport event if one is scheduled on the day. Since only 100 CEOs across the two countries are exposed to at least one match during the survey week, this test will inherently have less power than the earlier test to identify CEOs' responses.

For this analysis, we use total hours of work at the daily level (since this is the frequency at which the shocks occur) to estimate the following specification:

$$h_{id} = \alpha^F Fam_i + \gamma X_d + \beta Fam_i * X_d + C_i\rho + F_i\varphi + S_i\delta + I_i\eta + \varepsilon_{id} \tag{6}$$

where h_{id} is one plus the log of daily hours worked by CEO i on day d, $Fam_i = 1$ if CEO i belongs to the owning family as defined above, $X_d = 1$ if day d has extreme rainfall in Columns 1-4 and a sport match in Columns 5-8 and C, F, S, I are vectors of CEO, firm, and industry characteristics as defined in equation 4; standard errors are clustered at the firm and date level across all regressions. The coefficient of interest is β, the parameter measuring whether family and professional CEOs react differently to shocks increasing the marginal cost of effort.

The results of this estimation are shown in Table 6. Column 1 restricts the sample to Indian

[30]See the Appendix for details on the construction of the rain shock variable.

[31]In Brazil, since the data collection did not overlap with finals or semi-finals we focus on matches played by the top 30 teams (as measured by fanbase size). See the Appendix for details.

firms, and replicates our baseline specification controlling for the extreme rain dummy. The difference in hours worked between family and professional CEOs is in line with earlier estimates (8%), while the coefficient on extreme rain is negative, but not significant. In column 2 we include the interaction family CEO*rain. This shows that family CEOs reduce their hours on a rainy day significantly more than professional CEOs (coefficient -0.066, standard error 0.030). Columns 3 and 4 show that also in Brazil family CEOs are much more likely to react to rain shocks relative to professional CEOs. The coefficient is also negative and significant at the 10% level, with a similar magnitude (coefficient -0.071, standard error 0.041). The results are similar when we pool the sample across the two countries (see column 1 in Appendix Table A.10). [32]

According to the model, the differential reaction to common shocks identifies the sign of the difference in preferences if and only if the cost shock (rain) affects all CEOs equally regardless of firm governance. This assumption fails if factors correlated with firm governance type affect the effect of rain shocks on the marginal cost or the marginal product of CEO time, namely $cov(\varepsilon_{id}, Fam_i * Rain_d) \neq 0$. For example, firms run by family CEOs might have characteristics that make them more prone to be disrupted by rain (e.g., if they are more likely to have old machinery or bad maintenance processes). To test the robustness of the results to these factors, in Appendix Table A.10 we augment the specification with additional CEO and firms controls and interactions between rain and state, and between industry, CEO and firm characteristics. Reassuringly, the inclusion of these interactions does not generally affect the magnitude and precision of the difference in difference estimate allaying the concern that this captured unobservables at the firm day level.[33]

We turn to sport events in columns 5 to 8. Since the sport matches we consider are generally held in the evenings, we focus on the afternoon hours (after 1pm in India and after 3pm in Brazil), which we expect to be more affected by the shocks. Even in this case, family CEOs are more likely to reduce their hours in concomitance of sport events relative to days with no sport event, in both India and Brazil. This reduction is also larger relative to professional CEOs, who appear to be unaffected by the "shock"–the β coefficients is, respectively -0.141 and -0.276, both significant at the 5%. Appendix Table A.11 allows for a rich set of interactions between sport events and CEO, firm, industry and state characteristics. The magnitude of the β coefficient is generally stable across these more flexible specifications.[34]

[32]We checked in more detail whether this result was driven by professional CEOs increasing their hours during rainy days, rather than family CEOs reducing their hours. The results are driven entirely by family CEOs working fewer hours while professional CEOs hours worked remain stable on a rainy day.

[33]Across the experiments, the β coefficient retains a similar magnitude but turns insignificant when we include the set of CEO characteristics interacted with the rain dummy.

[34]Similar to the rain regressions, across the experiments, the β coefficient retains a similar magnitude but turns insignificant when we include the set of CEO characteristics interacted with the rain dummy.

Notes: *significant at 10%; ** significant at 5%; *** significant at 1%. This Table is based on day level data collected from CEOs in Brazil and India. All columns estimated by OLS. Standard errors under coefficient are clustered by firm and date in all columns. The dependent variable in columns 1-4 is the log of 1 plus the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during the survey day. The dependent variable in columns 5-8 is the log of 1 plus the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during hours potentially affected by the sport event (1pm-7pm in India and 3pm-9pm in Brazil). Family CEO=1 for those who own the firm or belong to the family that owns the firm, and 0 otherwise. "Rain" is a dummy denoting intense rainfall (relative to May in India and to July in Brazil) in the area and day where the CEO is located (data measured by the closest weather station, matched to the zipcode of the CEO activities for the day). "Sport event" is a dummy denoting that an Indian Premier League playoff, semifinal or final game was played on the day for the India sample, and that a soccer match including at least one top Brazilian team was played on the day for the Brazil sample. Industry dummies are two digits SIC codes. Firm characteristics are the log of one plus firm age, a dummy to denote foreign or domestic multinationals, the number of people reporting directly to the CEO, a dummy to denote whether the firm employs a COO, the number of CEO's sons and daughters holding a managerial position in the same firm. CEO characteristics are a dummy to denote CEOs holding a managerial or board position in another firm, the log of CEO age, the log of one plus number of years CEO has been employed in the firm, a dummy to denote CEOs holding a college degree, a dummy to denote CEOs holding an MBA or equivalent degree, a dummy to denote CEO that have worked or studied abroad. Noise controls include: a dummy to denote cases in which the time use data was recorded by the CEO's Personal Assistant; interviewer dummies; a dummy to denote CEOs who formally report to an executive Chairman; interview week dummies; a self reported score given by the CEO to rank the representativeness of the week and a dummy to denote weeks with a national or religious holiday.

Notes: *significant at 10%; ** significant at 5%; *** significant at 1%. This Table is based on day level data collected from CEOs in Brazil and India. All columns estimated by OLS. Standard errors under coefficient are clustered by firm, date and state in columns 1-4, and by firm and date in columns 5-8. The dependent variable in columns 1-4 is the log of 1 plus the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during the survey day. The dependent variable in columns 5-8 is the log of 1 plus the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during hours potentially affected by the sport event (1pm-7pm in India and 3pm-9pm in Brazil). Family CEO=1 for those who own the firm or belong to the family that owns the firm, and 0 otherwise. "Rain" is a dummy denoting intense rainfall (relative to May in India and to July in Brazil) in the area and day where the CEO is located (data measured by the closest weather station, matched to the zipcode of the CEO activities for the day). "Sport event" is a dummy denoting that an Indian Premier League playoff, semifinal or final game was played on the day for the India sample, and that a soccer match including at least one top Brazilian team was played on the day for the Brazil sample. Industry dummies are 10 two digits SIC codes. **Firm characteristics** are the log of one plus firm age, a dummy to denote foreign or domestic multinationals, the number of people reporting directly to the CEO, a dummy to denote whether the firm employs a COO, the number of CEO's sons and daughters holding a managerial position in the same firm. **CEO characteristics** are a dummy to denote CEOs holding a managerial or board position in another firm, the log of CEO age, the log of one plus number of years CEO has been employed in the firm, a dummy to denote CEOs holding a college degree, a dummy to denote CEOs holding an MBA or equivalent degree, a dummy to denote CEO that have worked or studied abroad. **Noise controls** include: a dummy to denote cases in which the time use data was recorded by the CEO's Personal Assistant, 15 interviewer dummies, a dummy to denote CEOs who formally report to an executive Chairman; interview week dummies; a self reported score given by the CEO to rank the representativeness of the week and a dummy to denote weeks with a national or religious holiday.

Mechanisms

Taken together, the results in this section are consistent with the idea that the leisure-performance tradeoff differs between family and professional CEOs or, in the terminology of our model, $c_P > c_F$.

While our data does not allow us to fully investigate the reasons behind the heterogeneity in the preference for leisure across CEOs, a candidate explanation consistent with our results is that these differences may be related to wealth differentials. Namely, family CEOs are likely to be wealthier than professional CEOs, since they own the firms they lead. If leisure is a normal good, this would result in differences in the leisure-performance tradeoff across CEOs.

To investigate this idea, we examine whether the differences in the hours worked by family CEOs vary according to cross-country differences in inheritance laws–the results of this analysis are presented and discussed in Appendix Table A.12. These laws are interesting from our perspective, since they create variation in wealth concentration (Ellul et al. (2010)), such that more permissive laws favor the concentration of wealth in the hands of the individual designated to inherit the control of the family business. Other things equal, we therefore expect family CEOs to be wealthier in countries where the maximal share of transmissible wealth is larger, and the difference between family and professional CEOs to be larger.

In line with this hypothesis, we find that the difference in hours worked between family and professional CEOs is increasing in the share of wealth that can be bequeathed to a single heir. To the extent that wealth concentration is correlated with wealth differentials between owners and managers, the result provides some indicative evidence that labor supply differences may be affected by wealth differences.

Another observationally equivalent explanation is that family and professional CEOs have similar preferences for leisure, but are subject to different performance-related incentives. For example, the compensation of family CEOs may be less sensitive to firm performance, or they may attribute a lower probability to the event of being fired for underperformance.

In absence of detailed data on CEO wealth and or firm level incentive policies, we cannot distinguish between these two alternative channels. We note, however, that both mechanisms–combined with the productivity results presented in Table 2–imply that potential profit opportunities may be lost in the pursuit of private benefits of control.

6 Conclusion

This paper shows evidence of a significant difference in behavior between family and professional CEOs, i.e. family CEOs tend to work fewer hours relative to professional managers. The difference between the two types of governance is not entirely accounted for by observable differences in firm, CEO and industry characteristics, and is larger when the opportunity cost of leisure is smaller. These patterns are consistent with the predictions of a simple model with heterogeneous preferences

for leisure between family and professional CEOs.

The data also reveals a strong correlation between CEO hours and firm performance. While no causal inference can be made, differences in hours worked can account for almost a fifth of the productivity difference between family and professional CEOs. The behavioral difference is hence a potential candidate to account for at least some of the performance differential between family and non-family firms documented in the literature (Morck et al. (1998), Villalonga and Amit (2006b), Pérez-González (2006), Bennedsen et al. (2007), Bertrand et al. (2008), Bertrand (2009)).

The question that follows naturally is: why don't family CEOs delegate to professionals who are willing to work longer hours, so to enjoy both more leisure and higher profits? One possibility is that family CEOs are unable to delegate due to costly contract enforcement and the subsequent perceived risk of expropriation on the part of non-family affiliated CEOs (Shleifer and Wolfenzon (2002)). As documented in the earlier literature (Burkart et al. (2003), Durnev and Kim (2005), Doidge et al. (2007)), this hypothesis is consistent with observed cross country differences in family controlled firms. Consistently with these findings, even in our limited cross country sample, we find that the share of family CEOs is significantly higher in developing countries, where governance is typically more problematic.

The evidence presented in this paper highlights the importance of how corporate leaders allocate their limited attention. Attention is a scarce resource, particularly so at the top of the organization. The allocation of time reflects the allocation of attention, which in turns depends on the strategic priorities of the CEO. The importance for effective corporate leaders of aligning their own time management to their goals has been a cornerstone of leadership theories for many years (Drucker (1966)). According to Simon (1976), "attention is the chief bottleneck in organizational activity, and the bottleneck becomes narrower and narrower as we move to the tops of organizations." Attention constraints at the top feature prominently in economic models of organizational hierarchies, which study how managers should allocate this resource optimally. This study documents differences in attention allocation at the top, but does not identify the channel through which they may affect firm performance. Halac and Prat (2016) model the effects of attention misallocation on the quality of management and the engagement of the workforce. Future research should investigate this and other possible channels for this effect.

Finally, our paper provides suggestive evidence that differences in wealth may have an effect of managerial labour supply. This finding raises a public finance question. Would an increase in taxation that affects the owners of family firms bring about an increase in productive efficiency? Such taxation might include an inheritance tax, a wealth tax, or a reduction in the various forms of exemptions that family firms enjoy in many parts of the world. We leave these questions for future work.

A Data Appendix

A.1 The Time Use Survey

A.1.1 Survey Management

The time use survey took place in two stages, both led by the same project manager: in the Spring of 2011 a team of fifteen enumerators and two supervisors based in Mumbai collected data on India, while the rest of the countries were covered in a second survey wave in the Spring of 2013 by a team of forty enumerators and six supervisors based at the London School of Economics. To ensure comparability, we adopted the same protocol and retained the same project manager across both waves. The enumerators were typically graduate students (often MBAs) recruited specifically for this project. All enumerators were subject to a common intensive training on the survey methodology for three days at the beginning of the project, plus weekly team progress reviews and one to one conversations with their supervisors to discuss possible uncertainties with respect to the classification of the time use data. Each interview was checked off at the end of the week by a supervisor, who would make sure that the data was complete in every field, and that the enumerator had codified all the activities according to the survey protocol. Each enumerator ran on average thirty interviews, with an average of three interviews per week to ensure data quality.

Each enumerator was allocated a random list of about 120 companies, was in charge of calling up the numbers of his or her list to convince the CEO to participate in the survey, and collecting the time use data in the week allocated to the CEO.

We actively monitored and coached the enumerators throughout the project, which intensified their persistence in chasing the CEOs and getting them to participate. We also offered the CEOs a personalized analysis of their use of time (which was sent to them in January 2012 to the Indian CEOs and in June 2014 to the rest of the countries) to give them the ability to monitor their time allocation, and compare it with peers in the industry.

A.1.2 Sampling Frame

The sampling frame was randomly drawn from ORBIS, an extensive commercial data set that contains company accounts for several millions of companies around the world. Our sampling criteria were as follows. First, we restricted the sample to manufacturing and additionally kept firms that were classified as "active" in the year prior to the survey (2010 in India and 2012 for the other countries) and with available recent accounting data.[35]These conditions restricted our sample to 11,500 firms. Second, we further restricted the sample to companies for which we could find CEOs contact details. To gather contact information we hired a team of research assistants based in Mumbai, London and Boston who verified the CEOs names and found their phone numbers and emails. This restricted the sample to 7,744 firms. Of these, 907 later resulted not to be eligible for the interviews upon the first telephonic contact (the reasons for non eligibility included recent

[35]For the Indian sample, we also restricted the sample to firms headquartered in the fifteen main Indian states. This excluded firms located in Assam, Bihar, Chandigarh, Chhattisgarh, Dadra, Daman and Diu, Goa, Himachal Pradesh, Jammu and Kashmir, Jharkhand, Orissa and Uttarakhand, each of which accounts for less than 3% of Indian GDP.

Activity 3:
meeting / HQ/ consultant

Start Time 10:30 AM

End Time 12:00 PM

Type: Meeting

When was the activity scheduled in agenda? 3) 1-2 weeks ago

If unscheduled, was the activity undertaken due to an emergency?

Did the activity take place inside the firm and/or HQ? Inside firm - at HQ

Where did the activity take place, relative to HQ? Same state

How many people were present at the activity, excluding the Executive? 1

Who participated in the activity, excluding the Executive? (check all that apply)

- People employed by firm INSIDERS ☐
- People not employed by firm OUTSIDERS ☑

What type of INSIDERS participated in the activity? (i.e. people employed by the firm) / Most JUNIOR person participating reports to the Executive?

- Finance ☐
- Marketing/Communication ☐
- Production/Logistics ☐
- Strategy ☐
- Human Resources ☐
- Business Unit Directors ☐
- Others ☐

If "Others", specify:

What type of OUTSIDERS participated in the activity? (i.e. people NOT employed by the firm)

- Clients ☐
- Suppliers ☐
- Banks ☐
- Investors ☐
- Lawyers ☐
- Management Consultants ☑
- Politicians ☐
- Government Officials ☐
- Journalists ☐
- Unions ☐
- Competitors ☐
- Others ☐

If "Others", specify:

			(0.030)	
ROCE				0.000
				(0.001)
Number of firms	6256	5993	4090	3492

Notes: *significant at 10%; ** significant at 5%; *** significant at 1%. All columns estimated by probit (marginal effects reported, robust standard errors under coefficient). The dependent variable in all columns is a dummy=1 if the CEO participated in the survey. The selection regression is run on the latest available year of accounting data. All columns include 2 digits SIC industry dummies.

bankruptcy or the company not being in manufacturing), and 310 were never contacted because the project ended before this was possible. The final number of eligible companies was thus 6,527, with median yearly sales of $53,000,000. Of these, we were able to secure an interview with 1,131 CEOs, although 17 CEOs dropped out before the end of the data collection week and were thus removed from the sample before the analysis was conducted.

The selection analysis in Table A.1 shows that firms in the final sample have on average slightly lower log sales relative to the sampling frame (coefficient 0.071, standard error 0.011). However, we do not find any significant selection effect on performance variables, such as labor productivity (sales over employees) and return on capital employed (ROCE).

A.2 Firm Data

A.2.1 Accounts

Accounting data were all drawn from ORBIS for all countries. The main exception is India, where employment figures are typically not published in the public accounts. Therefore, we gathered this information from the survey questionnaire.

In the regressions shown in Table 2 we restrict the sample to the three most recent years in the interval running from 2007 to 2011 in India and 2008 to 2012 for the rest of the sample, and use only years in which the CEO was in office. The summary statistics for this sample are shown in Table A.2.

Table A.2: Accounting Data: Summary Statistics

	Mean	Standard Deviation	Number of firms with available information
Number of Employees	1764.67	9287.85	617
Sales	336642.30	2076857.00	617
Capital	78335.56	466065.10	617
Profits per Employee	10.06	16.43	720
Tobin's Q	1.06	1.11	313
Investment	12150.15	73855.30	697
Wages	57256.50	476536.40	563

Notes: This table reports the summary statistics of the accounting data used in Table 2 and A.4. All data is expressed in real 2005 '000 US$, except for Tobin's Q.

A.2.2 Ownership

Ownership data is collected in interviews with the CEOs and independently checked using several Internet sources (e.g. The Economic Times of India, Bloomberg, etc.), information provided on the company website and supplemental phone interviews. We define a firm to be owned by an entity if this controls more than 25.01% of the shares; if no single entity owns at least 25.01% of the share the firm is labeled as "Dispersed shareholder". Family firms are defined as those where a family (combined across all family members, all second generation relative to the founder or beyond) are the largest shareholders. Founder firms are defined as those where the original founder of the company is the largest shareholder. For both family 2nd generation and founder firms, we distinguish between cases in which a family firm or the founder are also CEOs of the company, in contrast to cases in which a professional manager (i.e. a person not affiliated with the founder or the family) has been nominated CEO. In the analysis we combine founder CEO and family, 2nd generation CEOs in a single category (41% of the sample). The omitted category in all regressions includes family or founder owned firms with professional CEOs (16.2%), dispersed shareholders (22.5%), government (0.8%), private equity/venture capital (7.5%), private individuals who are not founders or heirs to the founders of the company (9.3%). In 2.7% of the sample, the firm was owned by joint venture with equal split of the ownership shares.

A.3 Industry Data

Our industry classification is the US SIC (1987). Each firm is allocated to each main two digit sector based on sales. We have 32 distinct two digit industries, and at least two companies for all of these industries except 4 (0.4% of the sample of firms).

The Lerner index of competition is constructed following Aghion et al. (2005) as the mean of (1-profit/sales) in the entire database excluding the firm itself for every three digit SIC industry, using accounting data relative to the six countries in our sample (data averaged between 2006 and 2010 for India and between 2008 and 2012 for the rest of the countries).

The import competition measure is built as real industry imports divided by industry sales, using STAN data produced by the OECD. The measure is obtained by taking averages across all countries in our sample for which the industry measures were available (France, Germany, UK and

US). The years used to build this measures are 2006 to 2008, i.e. the latest years for which the data was produced using the ISIC REV3 classification (the coverage of the countries included in our sample declines dramatically in the data produced using the ISIC REV4 classification).

A.4 Shocks

A.4.1 Rain Shocks

The climate data was extracted on 12/08/2011 from http://www7.ncdc.noaa.gov/CDO/cdodata.cmd. The data was merged with station coordinates (latitude and longitude), and these were in turn used to merge the data with the time use dataset using the date and zipcode of each of the activities recorded in the data (data matched with the closest station, distance computed by generating the vertical and horizontal distance using the latitude and longitude points and applying Pythagoras).

In India, the expected arrival of the Monsoons is around June 1st, starting from the southwestern coast of Kerala, and gradually covering the entirety of India by July 15th. Therefore, for the Indian sample the definition of days of intense rain is based on the comparison of the daily rainfall precipitation with the average precipitation in the pre-Monsoon month of May for the same station. We first compute a variable measuring for each day between June 1st and July 31st the change in precipitation relative to the average May values for the same station. We then define a variable "Extreme Rain" which takes value one if the change in rainfall lies in the third tercile of the overall distribution computed using data across all stations in the sample. Finally, we match the CEO time use information with the rainfall data of the closest weather station by using the modal (manually collected) zip code of the activities undertaken by the CEO during the week. We use the same approach in Brazil, but in this case we use as a reference the month of July of the year prior to the survey (2012), which is on average the driest month for the São Paulo region,[36] where 44.4% of the firms in the Brazilian sample are located.

The rainfall measure can be constructed for 597 CEOs in the sample. 32% of the CEO-day observations are classified as days of intense rain. 403 CEOs out of 597 CEOs (of which 215 family and 188 professional CEOs) experience extreme rain at least once during the survey week. 363 CEOs in the sample (186 family CEOs and 177 professional CEOs) have at least one day of extreme rain and one day of non-extreme rain during the sample week.

A.4.2 Sport Events

For the Indian sample, we use data on the 2011 Indian Premier League (IPL) Cricket tournament. We focus on four games: two playoffs (Royal Challengers vs. Chennai Super Kings, played on 5/25/2011) and Mumbai Indians vs. Kolkata Knight Riders, played on 5/25/2011), one semi-final for the 3rd and 4th place (Royal Challengers vs. Mumbai Indians, played on 5/27/2011) and the final (Chennai Super Kings vs. Royal Challengers (played on 5/28/2011). For the Brazilian sample, we use data on soccer matches played in the 2013 State Football Leagues. We focus on matched played by the top 30 teams (as measured by fanbase size).[37] These teams are located in the states of Bahia, Ceará, Goiás, Minas Gerais, Pará, Paraná, Pernambuco, Rio de Janeiro, Rio Grande do

[36] https://weather-and-climate.com/average-monthly-Rainfall-Temperature-Sunshine,sao-paulo,Brazil

[37] The source for the soccer match data is Resultados.com (http://www.resultados.com/futebol/brasil/). The source for fanbase data is a survey conducted by Pluri Stochos Pesquisas e Licenciamento Esportivo between November 2012 and February 2013. A total of 21,049 people were interviewed.

Sul, Santa Catarina, and São Paulo. The State Football League matches started in January and ended in May 2013, which coincided with the timing of our data collection.

The sport events dummy is constructed for 597 CEOs, 6% of the CEO-day observation are classified as days with a sport event. 100 CEOs out of 597 CEOs (of which 46 family and 54 professional CEOs) experience a day with a sport event and a day without a sport event during the survey week.

A.5 Wealth and the Demand for Leisure

While it is intuitive that the average family CEO, who owns a sizable share of the firm, may be wealthier than the average professional CEOs, who owns a small share of the firm (if any), a test of the hypothesis requires comparing the difference in hours worked at different levels of wealth differentials. Measuring personal wealth via surveys is notoriously difficult and we have no information, let alone a plausible source of variation, on the CEOs' wealth.

Instead, we approach this question using as a proxy for wealth differentials between family and professional CEOs exploiting cross-country differences in inheritance laws compiled by Ellul et al. (2010), which provide a country-specific measure of the largest share of the family wealth that can be bequeathed to a single heir. Intuitively, more permissive laws favor the concentration of wealth in the hands of the individual designated to inherit the control of the family business. Other things equal, we therefore expect family CEOs to be wealthier in countries where the maximal share of transmissible wealth is larger.

The variable "Max % of inheritable wealth" used in Table A.12 measures the largest share of the estate that in each country a testator can bequeath to a single child in presence of a surviving spouse and two siblings (Ellul et al show that the median number of children of firm owners is estimated to be two across almost all countries where this could be calculated). We use the measure published on Table 1, column 4 of the paper for all countries except for India. The measure proposed for India by Ellul et al is based on the Indian Succession Act, which applies to all non Hindu and non Muslim citizens. Since the vast majority (81%) of the Indian family firms in our sample are organized as Hindu United Family (HUF) organizations, we refer instead to the Hindu Succession Act (1956) which stipulates that the head of a HUF family firm must bequeath his share of the firm in equal parts to all members of the HUF. Since there must be at least two members in a HUF and we do not know the number of family members, we take 0.5 to be the upper bound of the inheritance share. Results are robust to assuming there are three surviving members hence the maximal share is 0.33.

To test whether this results in larger differences in hours worked between family and professional CEOs we estimate:

$$h_{ijc} = \alpha Fam_i + \beta Fam_i * (S_c - \bar{S}) + C_i\varphi + F_i\phi + \delta_j + \eta_c + \varepsilon_{ijc} \tag{A.1}$$

where S_c is the largest admissible inheritance share in country c and $\bar{S}$ is the sample mean. Standard errors are clustered at the country level and bootstrapped using the wild bootstrapping technique proposed by Cameron et al. (2008) given the small number of clusters. The coefficient of interest is β, the interaction between the family CEO dummy and the inheritance share variable. Under the assumption that the latter proxies for family CEOs wealth, the hypothesis that the demand for leisure is increasing in wealth implies $\beta < 0$. We scale S_c in deviation from its sample mean, so that the coefficient on the family CEO dummy α measures the difference between family

and professional CEOs at the mean values of S_c. S_c ranges from .5 (France and India) to 1 (UK and US).

Column 1, Table A.12 reports the estimates of (A.1). We find $\beta < 0$ and precisely estimated. Its magnitude implies that going from an average share of .69 to the highest share of 1 increases the difference in hours worked by .07 log points, 79% of the mean effect. In other words, family CEOs located in countries with the average level of the inheritance variable work 9% fewer hours than professional CEOs; those in countries with the highest level of the inheritance variable work 16% fewer hours than professional CEOs.

The inheritance variable may capture other country specific factors different from wealth concentration, which may also affect the labor supply of family CEOs. For example, differences in the quality of contract enforcement may affect the ability to delegate control to a professional CEO (Bloom et al. (2013)) and, therefore, the selection of family CEOs (intuitively, when delegation is feasible all family CEOs who have a higher marginal utility of leisure should delegate to hard working professionals and enjoy the extra profits these generate, while the only family CEOs who choose not to delegate should work as hard as professional CEOs). In Columns 2-5 of Table A.12 we check the robustness of the results to estimate (A.1) using different proxies of contract enforcement in lieu of S. Column 2 uses regional GDP, a country specific measure of the level of development (Gennaioli et al. (2013)), which is presumably correlated with the quality of contractual enforcement. Column 3 uses cross-country differences in the rule of law and Column 4 uses regional variation in the level of generalized trust, which we take as a proxy for the ease to manage incomplete contracts (Bloom et al. (2012)).[38] As above, we scale these variables in deviation from their sample means.

None of the interactions with these country-specific measures are significant. Finally, Column 5 includes together all the interactions between the family CEO dummy and all the proxies of contract enforcement, plus the interaction with the inheritance law variable discussed in the previous section. The latter remains of a similar magnitude and statistically significant at the 10% level.

[38] The Rule of Law measure captures perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement, property rights, the police, and the courts, as well as the likelihood of crime and violence. Estimate gives the country's score on the aggregate indicator, in units of a standard normal distribution, i.e. ranging from approximately -2.5 to 2.5. and is drawn from Kaufmann et al. (2010). Data on regional GDP per capita is drawn from Gennaioli et al. (2013). The measure is expressed in PPP constant 2005 international dollars. Data on regional trust has been calculated from the World Values Survey (WVS). The WVS is a cross-country project coordinated by the Institute for Social Research of the University of Michigan. Each wave carries out representative surveys of the basic values and beliefs of individuals in a large cross-section of countries. The questionnaire contains answers to specific questions about religion and social attitudes, including several question on generalized and specific trust (e.g. trust in the family, government etc.), as well as detailed information on the social and education background of the respondents (age, income, and education). The key question we use is the standard one: "Generally speaking, would you say that most people can be trusted or that you can't be too careful in dealing with people?". The WVS data can be downloaded from the WVS website (www.worldvaluessurvey.org). For the purposes of our analysis, we pool together four successive waves of data collection (1981–1984, 1989–1993, 1994–1999 and 1999–2004), and we use only individual entries with information on the respondents' region of residence. We compute the regional level of trust by taking the simple average over all observations available for the region across all WVS waves (see Bloom et al. (2012) for further details).

Notes: The table shows summary statistics (means, standard deviation in parentheses in columns 1-3; differences and t-statistic in parentheses in column 4) of CEO time use, CEO characteristics, firm and industry level data for a sample of 1114 CEOs in Brazil (N=282), France (N=115), Germany (N=125), India (N=356), UK (N=87) and US (N=149). All variables in Panel A, B and C collected in the CEO time use survey. Import penetration = ln(import/production) in the firm ISIC REV3 industry, computed by averaging OECD STAN data relative to the 2006–2008 time period (last available year for all countries) across France, Germany, US and UK at the industry level. Lerner index of competition = (1-profit/sales) in the firm 3 digit SIC industry computed, as in Aghion et al. (2005), by averaging firm level data in ORBIS relative to the 2008-2012 time period across Brazil, France, Germany, India, US and UK at the industry level.

Notes: *significant at 10%; ** significant at 5%; *** significant at 1%. All columns estimated by OLS (standard errors under coefficient clustered by firm). The variable "CEO Hours Worked" is the log of the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during the survey week. The dependent variable in columns 1 and 2 is log investments; in columns 3 and 4, log average wages.. Accounting data run between 2007 and 2013. Each column includes a full set of country by 2 digits SIC and year dummies. We include only years in which the CEO was in office in all columns, and allow for a maximum of three years of accounts for each firm (3 most recent years with non missing data in ORBIS). All columns include the following noise controls include: a dummy to denote case in which the time use data was recorded by the CEO's Personal Assistant; 55 interviewer dummies; a dummy to denote CEOs who formally report to an executive Chairman; 29 interview week dummy; a self reported score given by the CEO to rank the representativeness of the week and a dummy to denote weeks with a national or religious holiday.

Notes: The table shows summary statistics (means, standard deviation in parentheses in columns 1-3; differences and t-statistic in parentheses in column 4) of CEO time use, CEO characteristics, firm and industry level data for a sample of 1114 CEOs). All variables in Panel A, B and C collected in the CEO time use survey. Import penetration = ln(import/production) in the firm ISIC REV3 industry, computed by averaging OECD STAN data relative to the 2006–2008 time period (last available year for all countries) across France, Germany, US and UK at the industry level. Lerner index of competition = (1-profit/sales) in the firm 3 digit SIC industry computed , as in Aghion et al. (2005), by averaging firm level data in ORBIS relative to the 2008-2012 time period across Brazil, France, Germany, India, US and UK at the industry level.

Notes: *significant at 10%; ** significant at 5%; *** significant at 1%. All columns estimated by OLS. In all columns standard errors under coefficient are clustered by country (wild cluster bootstrap, Webb 6 point distribution). The variable "CEO Hours Worked" is the log of the total hours the CEO devoted to work activities lasting more than 15 minutes (excluding travel) during the survey week. Family CEO=1 for those who own the firm or belong to the family that owns the firm, and 0 otherwise. **Industry dummies** are 33 two digits SIC codes. **CEO characteristics** are a dummy to denote CEOs holding a managerial or board position in another firm, the log of CEO age, the log of one plus number of years CEO has been employed in the firm, a dummy to denote CEOs holding a college degree, a dummy to denote CEOs holding an MBA or equivalent degree, a dummy to denote CEO that have worked or studied abroad. **Firm characteristics** are the log of one plus firm age, a dummy to denote foreign or domestic multinationals, the number of people reporting directly to the CEO, a dummy to denote whether the firm employs a COO, the number of CEO's sons and daughters holding a managerial position in the same firm. **Noise controls** include: a dummy to denote cases in which the time use data was recorded by the CEO's Personal Assistant; 55 interviewer dummies; a dummy to denote CEOs who formally report to an executive Chairman; 29 interview week dummy; a self reported score given by the CEO to rank the representativeness of the week and a dummy to denote weeks with a national or religious holiday. The variable "Max % of inheritable wealth" is a country specific measure taken from Ellul et al (2010) for all countries, except for India where the measure is set to 0.50 to take into account the fact that the vast majority of family firms in our sample are organized as Hindu Undivided Family organizations (see main text for more details). The variables ln(GDP), region" and "Rule of Law, country" are taken from Gennaioli et al (2013). The variable "Trust, region" is computed using respondent level data from the World Values Survey and measures the % of people responding "Yes" to the question "Generally speaking, would you say that most people can be trusted or that you can't be too careful in dealing with people?".
