Abstract

To improve access to mental health care for children and adolescents, it is necessary to identify the barriers faced by their caregivers. The aim of this study is to identify these barriers in Greece and to investigate the reliability and validity of the modified version of the Barriers to Access to Care Evaluation scale (BACE) - the BACE Proxy Report (BACE-PR). A total of 265 caregivers who reported that their offspring had mental health difficulties completed the BACE-PR. Descriptive statistics were used to identify the major barriers to accessing care. Exploratory Factor Analysis (EFA) and Confirmatory Factor Analysis (CFA) were used to investigate the factor structure of the instrument. Item parameters were assessed via Item Response Theory. Interpretability was assessed by linking summed scores to IRT-based scores. Caregivers reported care costs, their willingness to resolve problems on their own, and their own concern that their children might be seen as weak, as the major barriers to services access. Obsessive compulsive symptoms and self-harm were the conditions for which caregivers reported the highest level of barriers. EFA and CFA suggested that a one-factor solution fit the data well (RMSEA=0.048, CFI=0.991, TLI=0.990). Internal consistency was found to be high ($\omega=0.96$). Average z-scores provided five meaningful levels of caregivers' perceived barriers compared to the national average. Caregivers face a variety of barriers to access mental health care for their children, and this could partly explain the treatment gap in the Greek mental health sector. Our study provides evidence for the reliability and validity of the BACE-PR scale, which can aid to identify caregiver-perceived barriers and to design interventions to improve access to mental health care.

Keywords Access · Barriers to care · Caregivers · Children · Mental health care seeking · Psychometric

Introduction

Nearly half of mental disorders emerge before the age of 18 (Solmi et al., 2022). It is well established that mental disorders are leading causes of disability and, if left untreated, may have a serious impact on educational achievement and social functioning (Arias et al., 2022; Egan et al., 2016; Schlack et al., 2021). Studies from all over the world, suggest that a large proportion of children with treatable mental health disorders do not receive the treatment they need to get better (Hall, S., Fildes, J., Perrens, B., Plummer, J.,

Carlisle, E., Cockayne, N., and Werner-Seidler, A. 2019; Merikangas et al., 2011; Raven et al., 2017; Whitney & Peterson, 2019). This treatment gap highlights the significant barriers to accessing care within each country's mental health system. To increase access to mental health care services for children and adolescents, it is crucial to thoroughly understand the factors that facilitate or inhibit their ability to receive care and to have reliable instruments that can assess those barriers accurately from parents' perspectives.

In child and adolescent mental health, caregivers play a major role in facilitating help-seeking and often serve as

Extended author information available on the last page of the article

the primary point of contact with mental health services (Hansen et al., 2021; Yurgelun-Todd, 2023). For in-person help seeking services, research has found that family is the dominant influence for adolescents (Rickwood et al., 2015). Caregivers, as key facilitators of their children's entry into mental health care, may encounter various barriers, including difficulties in recognizing symptoms, attitudes and stigma toward mental health that influence decisions to seek treatment, negative perception of mental health services, transport issues, flexibility of appointments and lack of knowledge about the appropriate type of care to seek (Collins et al., 2004; Drent et al., 2022; Logan & King, 2002; Owens et al., 2002; Teagle, 2002; Thornicroft et al., 2022; Yurgelun-Todd, 2023).

The literature on barriers to accessing either use an open-ended approach, asking caregivers to describe their reasons for not seeking help or the challenges they faced in accessing mental health services for their children (Eapen and Ghubash 2004; Shun Wilson Cheng et al. 2013) or employs predefined lists of barriers where caregivers indicate the presence or absence of specific barriers or rated them on Likert scale. Examples of such instruments include the Obstacle to Engagement Scale (Dumas et al. 2007), the barriers to participation scale (Kazdin et al. 1997) and Barriers to Treatment Utilization (Thurston and Phares 2008).

The literature on barriers to accessing mental health care from adults' perspective is limited in at least two important ways. First, quantitative studies -as noted above- typically using lists of barriers for caregivers to indicate their presence or absence or to rate them on a Likert scale, usually lack validation (Berger-Jenkins et al. 2012; Girio-Herrera et al. 2013; Larson et al. 2013; Shivram et al. 2009; Shun Wilson Cheng et al. 2013; Xiong et al. 2022). Second, while tools for measuring self-reported barriers in the adult population have validation studies, they are usually limited to specific contexts or populations (Pepin et al. 2015; Topkaya et al. 2016).

One of the tools that have the potential to overcome some of these challenges is the Barriers to Access to Care Evaluation (BACE v3) (Clement et al., 2012). The instrument may be used to identify key barriers to care experienced by individuals who currently use or have recently used secondary mental health services, and it shows potential utility for use with general population samples (Clement et al., 2012). Moreover, it assesses changes in barriers following intervention programs. The BACE has been developed as a self-report measure for adults experiencing mental health conditions and has been used in different countries (Alenezi et al., 2021; Fekih-Romdhane et al., 2024; Hongo et al., 2021). A multi-level conceptualization of barriers to accessing mental health care is supported by the Barriers to Access to Care Evaluation– Parent Report (BACE-PR), which

captures a diverse range of barriers, that may prevent caregivers from seeking support for their children. The BACE-PR allows for the identification of barriers across individual, social, and systemic levels. At the individual level, it captures concerns such as internalized stigma, negative beliefs about mental health care, or fears related to being judged as a parent. At the social level, it includes challenges stemming from perceived discrimination, school-related stigma, or fear of negative consequences in one's community or workplace. At the systemic level, the measure reflects structural and service-related obstacles, including difficulties accessing care, uncertainty about where to seek help, financial costs, lack of culturally appropriate services, and dissatisfaction with previous care experiences. By comprehensively addressing the diverse spectrum of potential barriers, the BACE-PR offers a nuanced perspective on the multifaceted factors—both individual and contextual—that can impede timely access to mental health services for children and adolescents.

Since BACE has been developed for adult population, validation for accessing barriers to care in the children and adolescents population is warranted.

Given this gap, as well as the fact that barriers may vary across countries due to cultural differences as well as differences in mental health system structure and facilities, the aim of the current study is twofold. First, we aim to investigate the children/adolescents caregivers' main perceived barriers to access to mental health care in Greece. Our second aim is to test the psychometric properties of the adapted version of BACE - PR scale as a proxy measure exploring its validity to be used by caregivers of children in need of mental health care.

Methods

Participants

We used data from a 2022/2023 cross-sectional survey from the Child and Adolescent Mental Health Initiative (CAMHI) on the current state and needs for child and adolescent mental health in Greece based on multiple viewpoints (Koumoula et al., 2024). A nationwide sample of 1,756 caregivers participated in the online survey, answering questions related to service use and access, literacy and stigma, parenting practices, and mental health needs of their children/adolescents. Out of them, 265 caregivers answered affirmatively to the question “*Does this child/adolescent have any mental health difficulty (any psychological problem, any problem with his behavior or learning) that you are aware of?*”. Subsequently they completed the BACE-PR scale. Recruitment occurred through an online

respondent panel provided by the research company IQVIA OneKey. This panel was developed based on census quotas, reaching participants online via social media and website campaigns, search engine optimization, panelists' friends referrals, and affiliate networks ("Kantar Profiles Audience Network" n.d.). To avoid self-selection, the online surveys were automatically routed to respondents based on a specific algorithm. Data was collected and preserved according to the General Data Protection Regulation (GDPR) National Policy (European Parliament and The Council, 2016). Ethical approval was granted by the Research Ethics Committee of the Democritus University of Thrace [approval number: ΔΠΘ/ΕΗΔΕ/42772/307].

Instrument

The Barriers to Access to Care Evaluation (BACE) scale was developed in the Health Services and Population Research Department of the Institute of Psychiatry, Psychology and Neuroscience, King's College, England (Clement et al., 2012). The BACE scale was originally developed as a 30-item self-report instrument conceived to evaluate barriers to access to mental health. Originally, authors suggest two subscales, the stigma subscale consisting of 12 items and the non-stigma consisting of the 18 remaining items. In the current study we used a modified version, adapted for assessing barriers to care for children and adolescents as reported by caregivers. The King's College London original lead author granted special consent for the adaptation.

BACE Adaptation to be a Proxy Measure in Greece

BACE was culturally adapted and translated in Greek, following reported detailed guidelines of a five-stage cultural adaptation process. Five stages included forward translation, synthesis of versions, back translation, expert committee review and pilot testing with population. The questions were modified at a pre-adaptation stage, to focus on children, e.g. "*Being unsure where to go to get professional care*" was modified to "*Being unsure where to go to get professional care for my child/adolescent*". Work-related questions were modified to reflect child/adolescent contexts e.g. "*Concern about what people at work might think, say or do*" was modified to "*Concern about what people at the school of my child/adolescent might think, say, or do*". In detail the five stages process included the following: Stage 1 involved a Greek forward translation conducted independently by two bilingual Greek native speakers with different backgrounds. The first translator was a child and adolescent psychiatrist with expertise in the concepts examined in the questionnaire, while the second translator, unfamiliar with mental health concepts, was a certified translator from an official

Greek translation company. Stage 2 involved synthesizing the two Greek translations. The two forward translators collaborated to resolve discrepancies and generate a unified translation. At Stage 3, validity checking was performed through independent back translation by two bilingual English native speakers with no medical or psychological training and they were unaware of the concepts being explored. One was an administrative member of our team, while the other was a certified translator based in the USA. At Stage 4, an expert committee reviewed the original questionnaire, all forward and back translations, and relevant documentation, reaching a consensus. The committee consisted of four Greek mental health experts, including child and adolescent psychiatrists and psychologists. Their decisions aimed to achieve semantic, idiomatic, experiential, and conceptual equivalence between the original and translated versions (Beaton et al., 2000). Stage 5 involved pilot testing, where the preliminary Greek version of the instrument was pre-tested with community samples to assess the clarity of each question and response item. Participant responses were reviewed by the expert team, and items that received feedback such as "I didn't understand anything" or "I understood a little," or that included concerning comments from most participants, were reformulated. In the final stage, the instrument was sent to the original author for input and final approval. As for the self-report (patient adult) measure, respondents (caregivers) should indicate whether each item has ever stopped or delayed or discouraged them from getting or continuing with mental health professional care for the child/adolescent they are responsible for (modified instruction to reflect children and adolescents). Scoring includes checking one of four possible answers: not at all (0), a little (1), quite a lot (2), or a lot (3) with higher scores indicating a greater barrier. For each barrier, according to authors, three different scores may be given; (a) the mean of the response scores, (b) the percentage reporting they have experienced the barrier to any degree (i.e. the % circling 1, 2 or 3) and (c) the percentage experiencing the barrier as a major barrier (i.e. the % circling 3).

Statistical Analysis

For the description of the BACE items, we used the mean score for each item and percentages as suggested by authors of the original scale. To explore which mental health difficulties seem to face more barriers, we plotted a heatmap of the mental health difficulties versus each barrier (item) of the BACE scale, representing the proportion of participants with a mental health difficulty that experience each of the BACE listed barriers.

Our psychometric assessment included several steps. First, since there are no studies that adapted the BACE scale

to a proxy version, we performed an Exploratory Factor Analysis (EFA) to explore its underlying structure by using the Maximum Likelihood Estimator (ML) and Geomin Oblique Rotation. The selection of factors was based on the scree plot of eigenvalues and on the factor loadings. After selection of the best model, a Confirmatory Factor Analysis (CFA) was performed to explore the fit of the model to our sample, by using the Pairwise Maximum Likelihood Estimator (PML). Model fit was evaluated with the following fit indices: the Comparative Fit Index (CFI), the Tucker-Lewis Index (TLI), the Root Mean Square Error of Approximation (RMSEA), and the Standardized Root Mean-square

Residual (SRMR). A good fit is indicated by the following values: SRMR<0.6; RMSEA<0.06; TLI and CFI>0.95 (Hu & Bentler, 1999). Reliability analysis was performed using Cronbach alpha and by Omega (ω) coefficient for our model. Cronbach alpha assumes equal loadings (essential tau equivalence) and a value of 0.7 is considered acceptable (“Psychometric Theory” n.d.). Omega estimates the proportion of variance in the observed total score attributable to all “modeled” sources of common variance. A value of >0.8 is considered strong (Kalkbrenner, 2023).

For interpretability- the degree to which one can assign qualitative meaning to an instrument’s quantitative scores or change in scores (Mokkink et al., 2010)- BACE has polytomous response options and therefore the graded response model (GRM) was used to estimate item parameters. We also conducted unidimensional item response theory assessments to determine where BACE provides information according to the latent trait. Moreover, we estimated the IRT factor scores of the latent variable to rank them into percentiles aiming to provide a meaningful scoring to stakeholders and researchers.

Analysis was performed using the software RStudio version 2023.12.1 (Mokkink et al., 2010; Posit team, 2024) and the packages *lavaan* (Rosseel, 2012), *psych* (Revelle, 2024), *ltm* (Rizopoulos, 2007), and *semTools* (Terrence D. Jorgensen and Sunthud Pornprasertmanit and Alexander M. Schoemann and Yves Rosseel 2022). Database sheets and the code is openly available at the following repository (<https://osf.io/crz6h/>).

Results

Participants

Sample characteristics are shown in Table 1. The majority of the respondents were female (59.6%) and were in a relationship (83.0%). Nearly all participants (98.1%) have finished the mandatory (9 years) education in Greece. The majority of caregivers reported that their child had learning difficulties ($N=95$), attention-deficit/hyperactivity disorder ($N=86$) and anxiety ($N=77$).

Barriers to Access to Care: Descriptive Assessment

Mean scores of each item of BACE are presented in Table 2, while percentages reported each item as a barrier to any degree and as a major barrier are presented in Fig. 1. All scores lie between 0.61 and 1.49 indicating that caregivers face overall barriers to a small degree. The barrier with the highest mean score is “Not being able to afford the financial costs involved” which concurrently is also the item

Table 1 Caregiver characteristic and reported child diagnosis

	Mean	SD

Other	14	5.2

*Total percentages of mental health difficulties exceed 100% since the item was a tickbox guiding caregivers to mark all that apply; ISCED=International Standard Classification of Education

Table 2 Mean scores, frequencies and ranks for each barrier in the barriers to access to care evaluation scale

No	Barrier	Mean	SD	% reporting barrier to any degree	% reporting as major barrier ('a lot')	Rank (1 = item has highest proportion rating as a major barrier)
11	Not being able to afford the financial costs involved.	1.49	1.06	77.48	20.72	1
2	Wanting to solve the problem of my child/adolescent on my own.	1.09	1.06	62.16	13.96	2
3	Concern that my child/adolescent might be seen as weak for having a mental health problem.	1.2	1.07	64.86	13.96	3
1	Being unsure where to go to get professional care for my child/adolescent	1.27	1.02	71.62	13.06	4
5	Concern that it might harm the child/adolescent's chances when applying for jobs in the future	1.03	1.08	55.86	12.61	5
20	Concerns about treatments available for my child/adolescent (e.g., medication side effects).	1.1	1.05	61.71	12.61	5
4	Fear of my child/adolescent being put in hospital against his/her will.	0.9	1.08	48.65	11.71	7
28	Concern about what people at the school of my child/adolescent might think, say, or do.	1.02	1.05	58.11	11.71	8
14	Concern that I might be seen as a bad parent.	0.94	1.06	52.25	11.26	9
7	Thinking the problem of my child/adolescent would get better by itself.	1.08	1.02	63.06	10.81	10
19	Concern that people might not take my child/adolescent seriously if they found out he/she was having professional care.	0.91	1.03	52.7	10.36	11
21	Not wanting a mental health problem to be on the medical records of my child/adolescent.	0.9	1.03	52.25	10.36	12
26	Concern about what the friends of my child/adolescent might think, say, or do.	0.95	1.05	52.7	10.36	13
8	Concern about what my child/adolescent's family might think, say, do or feel.	0.94	1.01	56.31	9.91	14
18	My child/adolescent dislikes talking about feelings, emotions, or thoughts.	1.05	0.99	63.51	9.91	15
25	Thinking my child/adolescent did not have a problem.	1	1.02	58.11	9.91	16
30	Having no one who could help me get professional care for my child/adolescent	0.94	1.02	54.95	9.91	17
24	Concern that the adolescent's children may be taken into care or that he/she may lose access or custody without his/her agreement.	0.77	1.01	44.59	9.46	18
29	Having problems with school while my child/adolescent receives professional care.	0.94	1	55.86	9.46	19
12	Concern that my child/adolescent might be seen as 'crazy'.	0.76	1.04	40.54	9.01	20
6	Problems with transport or traveling appointments.	0.92	1	54.95	8.56	21
13	Thinking that professional care for my child/adolescent would not help.	0.86	0.99	51.35	8.56	22
15	Professionals from the child/adolescent's own ethnic or cultural group not being available.	0.77	1.01	44.14	8.56	23
16	Being too unwell to ask for help for my child/adolescent.	0.77	0.98	46.85	8.56	24
23	Preferring to get help from family or friends for my child/adolescent.	0.8	0.98	48.2	8.11	25
22	Having had previous bad experiences with professional care for the mental health of my child/adolescent.	0.87	0.97	53.15	7.66	26
27	Difficulty taking time off work to take my child/adolescent to a health care service or professional.	0.93	0.99	54.95	7.21	27
10	Preferring to get alternative forms of care for my child/adolescent (e.g., traditional/religious healing or alternative/complementary therapies).	0.66	0.92	40.99	5.86	28
17	Concern that people I and my child/adolescent know might find out.	0.62	0.9	39.19	5.86	29
9	Feeling embarrassed or ashamed by my child/adolescent.	0.61	0.86	39.64	4.05	30

with the highest percentage reporting this as a barrier to any degree as well as reporting it as a major barrier. Other highly reported barriers include the fear that the child might be seen as weak, the willingness of the caregivers to solve the difficulties by themselves, the uncertainty of where they

should ask for help and the future consequences relating to job applications.

Figure 2 presents the barrier heatmap according to each reported mental health difficulty. Parents reported facing all barriers in high degree when their children presented with

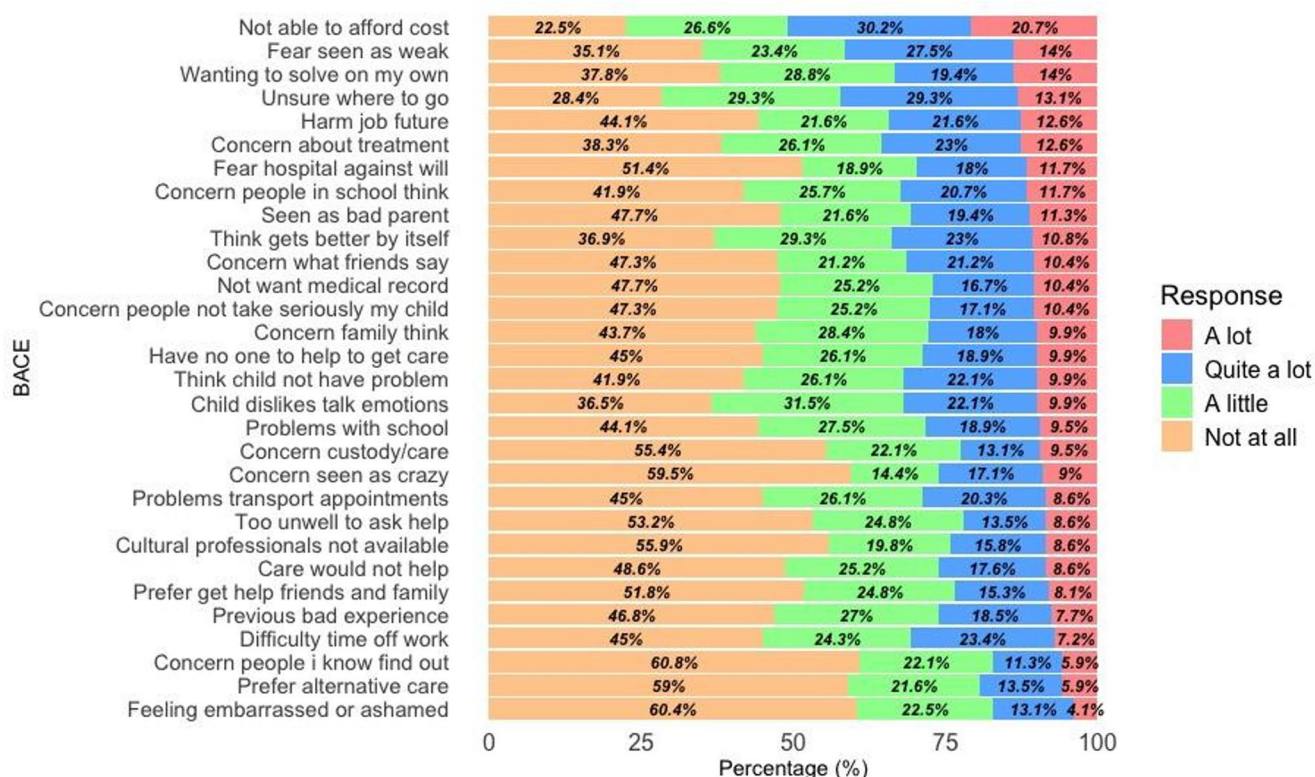

Fig. 1 Caregivers ratings in each response (in percentage) of how much (“a lot”, “quite a lot”, “a little”, “not at all”) each item ever stopped, delayed or discouraged them from getting, or continuing with, profes-

sional care for a mental health problem. Descending order based on the percentage reported as a major barrier (circling “A lot”)

delusions and hallucinations, while obsessive compulsive disorder was the disorder where caregivers encountered a lot of barriers. Other difficulties that face a lot of barriers in high degree include self-harm and intellectual disability. On the other hand, difficulties with a low level of barriers are mainly behavioral disorders as well as attention-deficit/hyperactivity disorder and autism spectrum disorder.

Exploratory Factor Analysis

The results of the scree plot (Figure S1, Supplementary Material) favored a unidimensional solution. All 30 factor loadings were very high (>0.6) except two that displayed values of 0.38 and 0.59, although still significant.

Confirmatory Factor Analysis

The unidimensional model (barriers to access to care) showed very good fit indices to the data (RMSEA=0.048, CFI=0.991, TLI=0.990, SRMR=0.061). Factor loadings were high, ranging from 0.38 to 0.89 (Table 3).

Reliability

Unidimensional model presented with high reliability with values of 0.96 to McDonald’s ω as well as Cronbach’s alpha, indicating excellent internal consistency (Table 3).

Interpretability

Unidimensional Item Performance Analysis. Item response function curves and item information curves for each item can be found in Figures S3 and S4, supplemental material. Test information function plot (Figure S5) shows that BACE proxy version provides the most information about slightly-above-than-average barrier levels (the peak is around $\theta=1$).

Linking summed score to IRT-based z-scores. Factor score from the IRT of the BACE proxy version as shown in Fig. 3 follows the normal distribution. The z-scores for the latent variable (Table 4) provide a reference point to assess interpretability of the BACE. Based on those scores, we classified the amount of barriers that caregivers face as: (1) No barriers (BACE total = 0); (2) slight barriers (BACE total 1–31); (3) mild barriers (BACE total 32–44); (4) moderate barriers (BACE total 45–63); and (5) severe barriers (BACE total over 64).

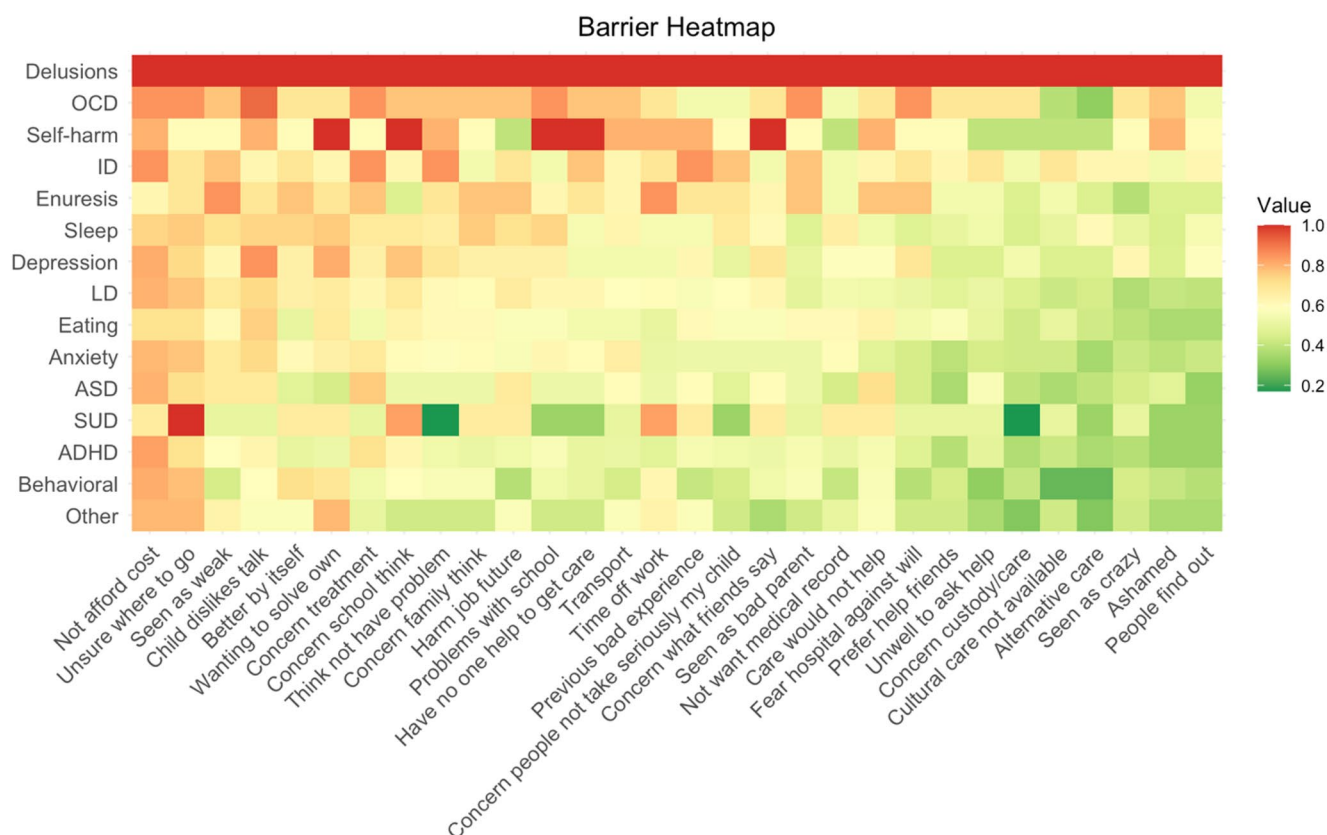

Fig. 2 Percentage of caregivers reporting each barrier to any degree (answer: “A little”, “Quite a lot”, “A lot”) in each diagnosis. Order of BACE items according to percentage reported to any degree (descend-

ing left to right). Order of the mental health difficulties according to the overall level of barriers based on the mean BACE item scores (descending up to bottom)

Discussion

The aim of this study was to identify the barriers that caregivers face to access mental health care in Greece for their children and to explore the reliability and validity of the culturally adapted BACE-PR in a nationwide sample of caregivers with mental health concerns of their children. The top five major barriers to access care in Greece were “Not being able to afford the financial costs involved”, “Wanting to solve the problem of my child/adolescent on my own”, “Concern that my child/adolescent might be seen as weak for having a mental health problem”, “Being unsure where to go to get professional care for my child/adolescent” and “Concern that it might harm the child/adolescent’s chances when applying for jobs in the future”. We showed consistent evidence for the reliability and validity of BACE-PR as a unidimensional construct. We also provide practical recommendations for interpretability of the BACE-PR by means of using IRT based scores (z-scores).

Several factors contribute to barriers in mental health care. It is well known that countries allocate on average only 2.1% of their total health budgets on mental health, resulting in limited resources (Knapp et al., 2006; World

Health Organization, 2021). Given the shortage of mental health professionals (Saraceno et al., 2007; World Health Organization, 2021) worldwide, limited recourses become more evident, leaving population needs unmet. Additionally, these longstanding challenges have been further amplified recently by the COVID-19 pandemic which led to an increase in mental health problems and consequently, an increased demand for services (World Health Organisation, 2020).

In general, these factors also apply to Greece (a country with approximately 10 million inhabitants) which was additionally affected by the financial crisis. At a political level, public funding for mental health was reduced by 20% between 2010 and 2011, and by an additional 55% between 2011 and 2012 (Anagnostopoulos & Soumaki, 2012). At an individual level, it is not surprising that one of our study’s most significant findings is that three quarters of caregivers reported financial costs as a barrier to accessing mental health care. We argue that this may be related to the consequences of 12 years of continuous financial crisis in Greece, which appeared to worsened due to increased demands following the COVID-19 pandemic. During the crisis years, unemployment rates rose, and income loss was observed

Table 3 Confirmatory factor analysis parameters and reliability coefficients

No	Item	Factor loadings	Thresh-old 1	Thresh-old 2	Thresh-old 3
1	Being unsure where to go to get professional care for my child/adolescent.	0.509	-0.594	0.179	1.127

across most professions. As a result, with reduced earnings, the population faced increasing difficulty in affording healthcare expenses. Moreover, mental health is known to be particularly vulnerable to rapid economic fluctuations (Durkheim, 2006; Economou et al., 2011; United Nations Publications, 2014). Notably, the proportion of the population that is at risk of poverty or social exclusion rose from

28.1% in 2008 to 36% in 2014 and 35.7% in 2015 (Stylianiadis & Souliotis, 2019). Consequently, demand for mental health services increased, while at the same time public mental health services operated with fewer employees (compared to pre-crisis years) with long waiting lists especially since the vast majority of child and adolescent psychiatrists work in the private sector (Kotsis et al., 2019; Marchionatti

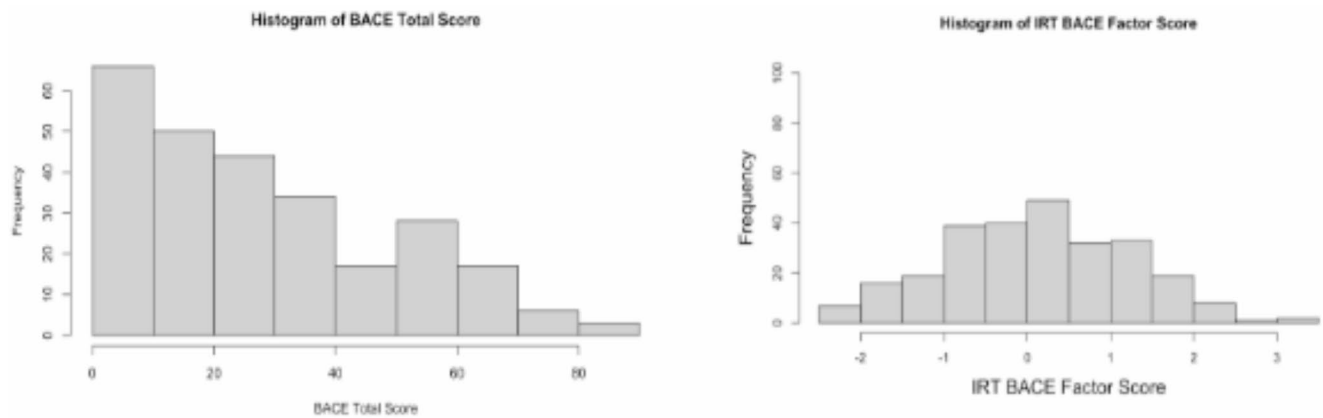

Fig. 3 Histogram of the BACE Factor score from the Item Response Analysis

et al., 2024). Although Greece has one of the highest ratios of child and adolescent psychiatrists per 100,000 young people (Signorini et al., 2017), a significant shortage persists in the public sector. This issue was further exacerbated by the financial crisis due to hiring freezes. However, the lack of Child and Adolescent Mental Health Services (CAMHS), particularly outside major urban centers, has long been a persistent challenge. Although the public mental health system is mainly free of charge, many caregivers seek care in the private sector. However, the cost of private treatment for children with mental and neurodevelopmental disorders is only partially covered by the national insurance fund, thus caregivers often have to pay out-of-pocket costs for their child's treatment. Moreover, since there are areas, especially rural ones, with total lack of child psychiatrists (even in the private sector), caregivers are struggling to find a physician to prescribe the interventions to be covered by the national insurance. Our finding is consistent with the international literature where in many studies the cost consistently emerges as a major barrier (Bussing et al., 2003; Harwood et al., 2009; Sawyer et al., 2004).

Another significant finding of our study is that a set of barriers to mental health access among caregivers of children with mental health problems in Greece are related to attitudes and stigma. Several studies in the literature suggest that these types of barriers are noted among caregivers (Cohen et al., 2012; Meredith et al., 2009; Pullmann et al., 2010). To our knowledge, no prior studies in Greece have explored caregivers' beliefs regarding barriers to their children's mental health services. However, stigma surrounding mental illness is prevalent in Greek culture according to a systematic review (Tzouvara et al., 2016). Finally, the lack of knowledge about where to refer for help also represents a barrier in our study, consistent with the literature (Cohen et al., 2012; Sayal et al., 2015; Stein et al., 2003). This may reflect the fragmentation of the Greek mental health system, the significant disparities in standards of care across both

public and private providers and the overall challenges the system faces in Greece (Loukidou et al., 2013; Petrea et al., 2020). Current initiatives aim to mitigate those barriers by improving public access to information (www.camhi.gr).

Based on our study, in Greece caregivers of children with psychosis, obsessive compulsive symptoms (OCS), self-harm behaviors, or intellectual disability (ID) seem to face the most barriers and to a higher level compared to caregivers of children with other disorders in our sample. These conditions are severe, often associated with significant impairment in everyday functioning and may need specialized services. Patients with psychosis do not seek help and face a lot of barriers (stigma, mental health literacy) while poor service engagement is common in adolescents (Birchwood et al., 1998; Skrobinska et al., 2024). Additionally, considering that psychotic patients may require inpatient treatment, our finding is not surprising given the significant lack of inpatient units in Greece (Marchionatti et al., 2024). Parents of children with OCD find themselves caught in "loops" engaging in repeated process steps due to the emergence of barriers, when they seek exposure therapy. They also feel isolated and guilty because of the burden of finding treatment for their children (Frank et al., 2023). Moreover, poor mental health literacy and stigmatizing attitudes contribute to delayed help seeking for OCD (Chaves et al., 2022). Similar reasons seem to apply to help seeking for young people at risk of self-harm (Aggarwal et al., 2021; Waller et al., 2023). It is well known that stigma is high for youth's self-harm behaviors and the care they receive in the emergency departments is often inadequate (Aggarwal et al., 2021; Cadorna et al., 2023; Zanusi et al., 2017). Caregivers of children with ID also indicate they face high levels of barriers that might be related to the barriers they also face in educational settings. Furthermore, when ID is comorbid with other disorders, such as autism spectrum disorders (ASD), it increases the likelihood of unmet mental health care needs (Menezes et al., 2021). Moreover, in the case of

Table 4 Interpretation of the barriers to access to care evaluation scale total score

Greece we should also highlight structural barriers such as the lack of specialized services providing evidence-based treatment for these conditions, especially in the public sector. On the other hand, our findings showed that behavioral disorders and other neurodevelopmental disorders such as autism spectrum disorder and attention deficit hyperactivity disorder face a lower level of barriers when compared to other mental health concerns. We hypothesize that externalizing problems as well as communication deficits and social impairment in ASD may prompt earlier help seeking, coupled with greater availability of private services in Greece that provide care for these conditions.

We also found that the psychometric testing of the BASE-PR provides good evidence for data quality and internal consistency. The unidimensional model fits the data well indicating that the BACE-PR can be used to measure the barriers that the caregivers face when they need to access mental health care for their children. The unidimensional solution seems in contrast with the literature considering that the original version of the BACE divides the items as stigma non-related and stigma (Clement et al., 2012), which was corroborated by the Arabic, the Japanese (excluding 6 items and with marginal fit indices) and the French versions (Alenezi et al., 2021; Fekih-Romdhane et al., 2024; Hongo et al., 2021). Our unique finding of unidimensionality might be explained by the fact that our tool represents a modified proxy version. Based on that, we suggest that the BACE-PR scale should be treated as a measure of the overall perceived barriers. In terms of practicality and interpretability, the results of this study can be used by stakeholders

to understand the quality and quantity of the barriers caregivers face. Reliability of our proxy version was also found very high, consistent with the above-mentioned translations.

Limitations and Strengths

Our study has important limitations. First, the sample size is small to conceptualize which barriers caregivers face in Greece and to explore measurement invariance across different groups. Future studies with larger sample sizes will also enable the identification of barriers faced by caregivers from diverse backgrounds (e.g., minorities) or other demographic groups, such as those living in rural areas or low-income families, where barriers appear to be distinct (Crumb et al., 2019). The sample size also prevented us from conducting EFA and CFA in distinct samples, as recommended by the literature for psychometric assessment of psychological instruments (Lorenzo-Seva, 2022; Schmitt et al., 2018). Second, this is an online panel-based sample, thus implying representative bias for groups without internet access. Moreover, a key limitation of this study is its cross-sectional design, which precludes the assessment of test-retest reliability. Finally, a limitation of the translation procedure is the lack of an assessment of experts' agreement on the content validity of each item. Our study also has strengths that should be highlighted. To the best of our knowledge this is the first study using a modified version of BACE, providing the international community with a tool to assess barriers to accessing care in children and adolescents. In addition, it is the first study in Greece exploring the

barriers that caregivers face in accessing to mental health care. Second, we followed a rigorous cross-adaptation process for the instrument. Third, item performance analyses in a nationwide survey, provided psychometric evidence of BACE-PR adequacy on an item-based approach, surpassing the limitations of classical test theory analyses. Finally, our study provides Greek service providers and stakeholders with a valid tool to record caregivers' perceived barriers to design interventions to address them.

Conclusions

In this study, we developed and validated the BACE-PR tool, addressing a gap of tools for caregiver report of barriers to child and adolescent mental health care. Caregivers of children with mental health concerns may encounter numerous barriers when help from mental health professionals is needed. Identifying them is important to understand the treatment gap at both the national and at the local level considering the different needs across the country, especially in terms of the uneven distribution of services and professionals. The network of interrelated barriers we identified, emphasizes the imperative for a coordinated, multi-tiered intervention strategy. Financial difficulties emerged as a key obstacle, reinforcing the urgency of providing free-of-charge, specialized services to ensure that economic hardship does not prevent families from accessing care. In parallel, stigma and limited awareness about mental health remain significant deterrents to help-seeking, highlighting the importance of public education and anti-stigma initiatives aimed at caregivers and communities. Beyond individual and social factors, systemic challenges such as lack of information about available services further compound difficulties in accessing care. Addressing these barriers requires practical solutions such as service mapping, clear referral pathways, and improved accessibility of culturally responsive services. Taken together, the findings point to the need for comprehensive strategies that engage all levels of the care system—from individual and family-level interventions to community and structural reforms. Such an approach is essential to promote timely, equitable, and effective mental health support for all children and adolescents, particularly those from underserved or vulnerable populations.

To improve access to treatment and to provide early and comprehensive services, we also need to explore variations in the perceived barriers among caregivers of children across different mental health disorders and different ages. Finally, the present study supports the use of BACE-PR to identify perceived barriers. Future studies on larger scale populations based on this tool are needed to confirm our findings.

Furthermore, appropriate interventions may be applied by policy makers to address the barriers, and longitudinal studies may evaluate their effect on children's mental health in Greece. Moreover, specifically addressing barriers at a more regional level can also be a positive strategy for fighting barriers considering the different needs across the country, especially in terms of the uneven distribution (against rural areas) of services and professionals. Diminishing the barriers and therefore increasing access to mental health care would be extremely beneficial for children and adolescents, since it will allow for early intervention and overall decrease the treatment gap.

Acknowledgements The Stavros Niarchos Foundation (SNF) under its Global Health Initiative has partnered with the Child Mind Institute and a countrywide Network of mental health providers in the public system to jointly design, launch, and deliver the Child and Adolescent Mental Health Initiative (CAMHI) in Greece, which supports this work. The authors would like to thank SNF's Co-President Andreas C. Dracopoulos and CMI's President Dr. Harold Koplewicz for their leadership in creating, launching, and supporting this project. We would also like to thank Ms. Elianna Konialis, Ms. Dimitra Moustaka and Mr. Panos Papoulas for their critical role in multiple steps of the conceptualization and implementation of the CAMHI objectives. Finally, thanks to CAMHI hub leaders and hub members that participated in multiple stages of this work and participants and their families for their contribution.

Authors' Contribution Konstantinos Kotsis and Giovanni Abrahao Salum have drafted the work. Data analysis was performed by Konstantinos Kotsis and Giovanni Abrahao Salum. Material preparation and data curation were performed by Konstantinos Kotsis, Julia Luiza Schafer, Lauro Estivalet Marchionatti, Alexandra Tzotzi, Andromachi Mitropoulou, Graham Thornicroft and André Simioni. Formal analysis was performed by Konstantinos Kotsis, Mauricio Scopel Hoffmann and Giovanni Abrahao Salum. Project administration was performed by Konstantinos Kotsis, Katerina Papanikolaou, Maria Basta, Aspasia Serdari, Anastasia Koumoula and Giovanni Abrahao Salum. Giovanni Abrahao Salum supervised the work. All authors contributed to data presentation; visualization by Konstantinos Kotsis, Caio Borba Casella and Giovanni Abrahao Salum. All authors substantially contributed to interpretation of data, reviewed and edited the work. All authors read and approved the final manuscript. All authors have agreed both to be personally accountable for the author's own contributions and ensure that questions related to the accuracy or integrity of any part of the work, even ones in which they are not personally involved, are appropriately investigated, resolved, and the resolution documented in the literature.

Funding Open access funding provided by HEAL-Link Greece. This work was fully funded by The Stavros Niarchos Foundation through The Child and Adolescent Mental Health Initiative (CAMHI).

Data Availability The dataset is openly available in the CAMHI Open Science Framework repository [<https://doi.org/10.17605/OSF.IO/CRZ6H>].

Code Availability The statistical codes supporting the conclusions of the current study are openly available in the CAMHI Open Science Framework repository [<https://doi.org/10.17605/OSF.IO/CRZ6HJ>].
