Summary

With this paper, we introduce the Marketing Strategy Conference approach to set strategic marketing priorities effectively and allocate marketing-related resources accordingly. The system is based on managerial preference modelling with a decision model (analytical side) and communication-enhancing strategy conferencing (interactive side). After a review of alternative resource allocation frameworks, as over-the-thumb approaches, matrix-based analyses, statistical analyses or management science models, we analyse existing analytical, behavioural and organisational impediments to effective marketing resource allocation. Addressing some of this impediments, this papers outlines two Marketing Strategy Conference cases, which we carried out for the pharmaceutical, Schering Argentina.

Introduction

“Formal systems, mechanical or otherwise, have offered no improved means of dealing with the information overload of human brains ... All the promises about artificial intelligence, expert systems, and the like improving if not replacing human intuition never materialized at the strategy level. Formal system could certainly process more information, at least hard information. But they could never internalize it, comprehend it, synthesize it.” – Mintzberg, 1994 (p.111)

The idea of supporting strategic marketing decisions with computer-based models goes back at least to the middle of the 1960's (Kuehn, 1965; Little and Lodish, 1969a; Montgomery and Urban, 1969). The core idea is to combine the adaptable, but sometimes biased judgements of marketers with the consistent, but sometimes rigid data processing capabilities of formal models (Li, 2005). Models include amongst others, Artificial Neural Networks (Poh, 1994; Chien, 1999), fuzzy logic (Levy and Yoon, 1995; Kuo and Xue, 1998), expert information systems (McDonald and Wilson, 1990; Alpar, 1991) and case-based approaches (Chiu, 2002; Changchien and Lin, 2005). Li et al (2000) provides a review of these approaches.

Reflecting Mintzberg's quote above, the results for effective applications of model-based support in marketing decision making, however, are mixed. The application of formal systems is usually limited to a narrow domain. Ill-defined decision problems with multiple objectives in the face of uncertainty, common in practice, are difficult to capture in a simple computer model. Consequently, a survey with marketing managers of manufacturing companies in the UK indicate widespread dissatisfaction with computer-based systems used in developing marketing strategies (Li et al., 2000). In particular, most systems fail to aid strategic thinking and to couple strategic analysis with managerial judgments.

To address this dissatisfaction, this paper aims to introduce a system - Marketing Strategy Conferencing (MSC) - with an analytical and an interactive component to aid marketing managers set strategic marketing priorities effectively and allocate resources accordingly. Analytically, MSC builds on recent advances in the area of decision analysis in order to provide marketers with insights in efficient trade-offs between strategic marketing initiatives. We are looking in particular at investments in different marketing programs (direct customer service activities, loyalty programs, direct advertising, etc.) or trade-offs between marketing activities for different product groups. Besides this analytical component, the system is interactive by providing organisations with a discussion framework to create strategic consensus, i.e. shared understanding on marketing priorities (Rapert et al., 2002). The system is designed to combine the operational bottom-up knowledge of marketing managers with the strategic vision of top-level management. The aim of the interactive component of the system is thereby to contribute to bridging the gap between marketing strategy formulation and implementation (Bonoma, 1984; Bonoma and Crittenden, 1988; Cespedes and Piercy, 1996; Lane and Clewes, 2000).

The rest of the paper is structured as follows: in the next section, we outline some existing methodologies to analyse strategic marketing prioritisations and to allocate resources accordingly. We then highlight analytical, behavioural and organisational impediments which hinder effective priority setting in marketing. Addressing some of these impediments we, thirdly, introduce the Marketing Strategy Conferencing approach, applied to two cases in the pharmaceutical, Schering Argentina.

Resources Allocation Methodologies For Marketing-related Decisions

Frameworks to set marketing priorities and to allocate resources are numerous. As displayed in Table 1, at least four classes of these methods exist:

- 'over-the-thumb' approaches (resource allocation heuristics), such as the percentage-of-sales method (Piercy, 1986; Lilien and Rangaswamy, 2003; Dibb et al., 2006; Kotler and Keller, 2006),
- matrix-based strategic approaches, including the BCG growth/share matrix or the directional policy matrix (Henderson, 1979; Wind and Mahajan, 1981; Morrison and Wensley, 1991; Baker, 2000)
- statistical analyses, mostly based on complex regression models (Blattberg and Deighton, 1996; Thomas et al., 2004; Reinartz et al., 2005)
- decision modelling approaches, including linear programming models, the Analytical Hierarchy Process or Multiple-Criteria Decision Analysis (Kuehn, 1965; Little, 1976; Davies, 1994; Richardson, 2004; Phillips and Bana e Costa, 2006).

'Over-the-thumb' Approaches (Resource Allocation Heuristics)

In particular when setting advertising budgets, various simple 'over-the-thumb' methods to allocate resources exist. Methods range from allocating budgets according to what managers consider their company can afford (Piercy, 1986; Piercy, 2002), to setting marketing objectives and allocating budgets to achieve these targets (Piercy, 1986; Dibb et al., 2006). Other common approaches include spending a fixed percentage of (current or forecasted) sales or to match the marketing expenditures of competitors or an industry (Piercy, 2002). Although 'over-the-thumb' approaches can be applied in a time saving manner, they are based on arbitrary assumptions, such as that sales creates advertising, rather than vice versa or they ignore the fact that competitors might have completely different

marketing objectives (Dibb et al., 2006; Piercy, 1986; Lilien and Little, 1976; Dalrymple and Thorelli, 1984).

Matrix-based Strategic Approaches

To provide a more structured framework for strategic marketing decisions, The Boston Consulting Group introduced the growth-share matrix in the 1970's (Henderson, 1979). As market growth is only a rough proxy for market attractiveness and as market share only partially captures competitiveness, more-dimensional approaches have won wider acceptance in the last few decades. Shell's Directional Policy Matrix or the business profile matrix, for example, offer a multiple factor framework to analyse portfolios (for a review of matrix-based approaches see Wind and Mahajan, 1981). Matrix-based portfolio analyses usually aim to classify and compare a firm's products or services in order to analyse optimal investment strategies for each product or service. In most cases, one axis represents internal factors such as the competitiveness of the firm's products, and the other, external factors, such as market opportunities (Day, 1977; Wensley, 1981; Brown, 1991; Morrison and Wensley, 1991; Dibb et al., 2006).

Despite their wide applicability in practice, matrix-based portfolio analyses have been criticised for being too generic to provide a sound basis for marketing strategy development (Wensley, 1981). With the BCG matrix, for example, decision makers do not obtain guidance on which 'problem child' to invest in or how many 'cash cows' to maintain. In addition to this over-simplification issue, the definition of categories, cut-off points and markets, influence the results of matrix-based portfolio analyses significantly. Matrix-based portfolio approaches can therefore be misleading when allocating budgets or developing strategies (Day, 1977). Another criticism of matrix-based approaches focuses on the underlying 'classical' product-life-cycle, which has been criticised for not being universally applicable (Dhalla, 1976).

Statistical Analyses

A more recent development is statistical analyses, which aim to provide guidance for an efficient allocation of marketing-mix related resources. These approaches are usually based on complex regression models to determine how much and where to spend marketing resources. Thomas et al. (2004), for example, introduced the Allocating Resources for Profits (APRO) approach, which aims to determine optimal investments by balancing spending between retaining old and attracting new customers. As one of the earlier statistical approaches, Blattberg and Deighton (1996) chose customer equity as resource allocation criterion for maximising the firm's long-term profitability. Using more advanced statistical models Venkatesan and Kumar (2004) as well as Rust et al. (2004) analyse strategic marketing initiatives based on their discounted customer life time value. In comparison to the other approaches, statistical analyses offer precise calculations on how much to spend in different marketing expenditures. On the other hand, the complex calculations and the lack of interactive models to discuss strategic issues are the potential drawbacks of these approaches.

Decision Modelling Approaches

Researchers have been developing decision models since the 1960's to aid marketing strategy development as well as the allocation of marketing resources (see for example, Kuehn, 1965; Montgomery and Urban, 1969; Little and Lodish, 1969b; Lodish, 1971; Vargas and Saaty, 1981; Nguyen, 1985; Mazanec, 1986; Eliashberg et al., 2002; Richardson, 2004). Linear programming models, the Analytical Hierarchy Process and multiple criteria decision models have so far been the most prevalent management science approaches to marketing-related decisions.

Linear programming models use an optimisation function (such as maximising sales) and constraints (such as a budget) to calculate optimal resource allocations (Hillier and Lieberman, 2005). Due to the complexity and lack of adaptiveness of early linear programming models, Little (1976) introduced more simple marketing science models. Following his 'Decision Calculus' school, researchers developed software based tools to help marketing managers allocate resources and develop marketing strategies. MEDIAC, for example, deals with selecting media options to create a media schedule (Little and Lodish, 1969a). CALLPLAN guides a salesperson in optimally allocating their time with customers (Lodish, 1971). SPRINTER allocates effort to marketing activities for the launch of a new product (Urban, 1970). Lodish, Curtis et al. (1988), used a custom model to analyse the optimal sales force size and how an organisation should deploy it. For a brief review of these approaches, see Richardson (2004). Linear programming models have been applied successfully in practice, nonetheless it remains challenging to build models which are sufficiently complex to capture the whole picture of a decision situation and, at the same time, remain sufficiently simple to be usable (Lodish, 2001).

Whereas linear programming approaches usually optimise a single criterion, such as profit or sales, the Analytical Hierarchy Process (Saaty, 1977, 1980) is able to deal with marketing-related trade-off problems. The Analytical Hierarchy Process (AHP) serves to structure portfolio decisions in hierarchical representations including different options and different objectives for the evaluation of the options (Davies, 1994). The AHP was used to aid in lease versus buy decisions in industrial purchasing (Vargas and Saaty, 1981), new product screening (Calantone et al., 1999), marketing mix strategy, new product development (Wind and Saaty, 1980), and advertising budget optimisation (Mazanec, 1986). Although the process simplifies cognitive demands on the decision makers by using pairwise comparisons of options (Davies, 2001), researchers have challenged the theoretical soundness of the

Analytical Hierarchy Process. According to Dyer (1990), for example, the AHP can lead to arbitrary, rather than systematic rankings of decision alternatives.

Finally, models based on multiple attribute utility theory (Keeney and Raiffa, 1976) can capture trade-offs between conflicting objectives in a theoretically consistent way. These conflicting objectives might include growth of market share, short-term profitability, image effects or the reduction of risk. Using this approach, Phillips and Bana e Cost (2006) combine simple preference modelling with communication-enhancing decision conferencing (Phillips, 2006) for an efficient allocation of resources and strategic group alignment. They are therefore in particular suitable for the Marketing Strategy Conferencing approach, as introduced below. Major drawbacks of multiple criteria models include difficult judgments on the part of the decision makers, in particular when weighting dimensions.

Table 1 gives an overview of the four approaches to allocate resources in marketing-related decisions, as discussed above.

Resource Allocation Frameworks for Marketing Decisions				
	Core Concept	Examples	Major Advantages	Major Drawbacks
'Over-the-thumb' Approaches (Heuristics)	Simple approaches without extensive quantitative analyses	<ul style="list-style-type: none"> - Affordability approach - Objective and task method - Percentage-of-sales approach - Competition matching approach (see Lilien and Little, 1976; Dalrymple and Thorelli, 1984; Piercy, 1986; Lilien and Rangaswamy, 2003; Dibb et al., 2006) 	Time saving 'just-enough' approaches	<ul style="list-style-type: none"> - Approaches are partly arbitrary - Approaches rely on false assumptions
Matrix-based Strategic Approaches	Simultaneous analysis of several resource allocation options, usually related to market attractiveness (external) and competitive capabilities (internal)	<ul style="list-style-type: none"> - BCG Growth/Share Matrix (Henderson, 1979) - Directional Policy Matrix (Shell, 1975) - Business Profile Matrix (Wright, 1978) 	High-level overview of the strategic positioning of different products/SBU, etc.	<ul style="list-style-type: none"> - Oversimplification - Very generic insights into efficient allocation of resources - Problems with definitions of categories, cut-off points and weights of dimensions
Statistical Analyses	Analysis of marketing-mix related resources based on complex statistical modelling (usually regression analyses)	<ul style="list-style-type: none"> - Allocating Resources for Profits - APRO (Thomas et al., 2004) - Maximising customer equity, i.e. customer life time value as resource allocation criterion (Blattberg and Deighton, 1996, Rust et al., 2004; Venkatesan and Klumar, 2004) 	Precise calculations on how much and where to spend marketing resources	<ul style="list-style-type: none"> - Complicated algebra ('black-box' problems) - Lack of interactive component to create strategic consensus and commitment to implementation
Decision Modelling Approaches	Decision models with a special emphasis on including managerial judgments to allocate marketing resource efficiently	<ul style="list-style-type: none"> - Linear Programming Models (reviewed by Richardson, 2004) 	Precise recommendations on how to spend resources, in particular when only monetary dimensions matter	<ul style="list-style-type: none"> - Models can be complicated to understand ('Black-box' problem)
		<ul style="list-style-type: none"> - Analytical Hierarchy Process (Saaty, 1977, 1980) 	Pair-wise comparisons facilitate easy managerial judgements	<ul style="list-style-type: none"> - Approach can lead to inconsistent results (Dyer, 1990)
		<ul style="list-style-type: none"> - Multiple-Criteria Decision Analysis (Keeney and Raiffa, 1976; Phillips and Bana e Costa, 2006) 	Consistent integration of financial and non-financial objectives; emphasis on strategic consensus finding through visual group decision support	<ul style="list-style-type: none"> - Managerial judgments can be difficult, in particular when weighting criteria

Table 1 – Various Resource Allocation Frameworks for Marketing Decisions

Despite the availability of an array of different methodologies to set marketing priorities and allocate resources accordingly, several impediments hindering effective marketing resource allocation remain.

Impediments Hindering Effective Marketing Resource Allocation

In the following section, we use the analytical, behavioural and organisational marketing planning dimensions of Piercy and Morgan (1990) to classify current impediments to the effective setting of strategic marketing priorities.

Analytical Impediments

Analytical impediments refer to the lack of analytical capabilities and structured methods when allocating marketing resources. The most common analytical impediments are *short-term thinking* and *incrementalism*.

The focus on quarterly reports, prevalent in many publicly listed companies, can lead to short-term thinking. A lack of strategic analysis when developing tactical resource allocations (Simkin, 2002) as well as an over-emphasising of short-term sales figures rather than market share growth (Webster, 1988; Dibb, 1997) can be the possible consequences. It can lead to investment in 'established', less risky marketing activities at the expense of new ones (Bonoma and Crittenden, 1988) or the investment in too many short-term focused sales promotions at the expense of advertising (Low and Mohr, 1999).

In particular when changing budgets or during annual planning procedures, another common pitfall is 'incrementalism' - changing budgets in a mechanical process only marginally in relation to the status quo (Piercy, 1986; Piercy and Morgan, 1990). In these cases, 'historical precedent' is the basis for marketing budgeting rather than strategic marketing opportunities (Dalrymple and Thorelli, 1984).

Behavioural Impediments

Besides these analytical shortcomings, in particular the *lack of vertical communication*, *lack of strategic consensus* and *lack of commitment to implementation*, can be several motivational reasons for ineffective strategic resource allocation in the marketing domain.

Lack of vertical communication across hierarchies in strategy development processes can lead to inferior strategies (Wooldridge and Floyd, 1990), which in turn can result in lower organisational performance (Floyd and Wooldridge, 1997; Noble and Mokwa, 1999). More involvement in marketing strategy development, on the other hand, can lead to an enhanced search for more alternatives and more diverse information (Collier et al., 2004). This accounts in particular for the involvement of middle management (Dutton et al., 1997; Floyd and Wooldridge, 1997; Floyd and Wooldridge, 1992; Wooldridge and Floyd, 1990) and the enabling of dissent rather than consent (Dooley and Fryxell, 1999). Involvement can also lead to the better alignment of groups through shared strategic understanding and a greater commitment to a joint way forward (Phillips and Bana e Costa, 2006).

Insufficient involvement (Wooldridge and Floyd, 1989) or internal communication efforts (Dibb, 1997) can thereby lead to a lack of strategic consensus on marketing priorities (Rapert et al., 2002). In this context, the area of marketing is in particular suitable for the creation of strategic consensus due to its boundary-spanning role (Rapert et al., 2002). Besides this lack of vertical communication, the separation between formulating marketing strategies, for example, through structured annual planning, and implementation can be drivers for a lack of commitment to the implementation of marketing strategies (Bonoma, 1984; Bonoma and Crittenden, 1988; Piercy, 1990; Piercy and Morgan, 1990; Cespedes and Piercy, 1996; Harris, 1996b, 1996a; Noble and Mokwa, 1999; Lane and Clewes, 2000; Thomas, 2002).

Organisational Impediments

Finally, organisational impediments – the lack of organisational structures for effective allocation of resources – can hinder effective marketing priority setting.

Viewed from a top-down perspective, organisations tend to distribute resources equally among their departments or organisational units, rather than applying transparent criteria to allocate resources efficiently (Fox et al., 2005). Similar to Hardin's (1968) common's dilemma, the overall result for the organisation can be inefficient, even if every unit is using their resources efficiently. Quick-growing business units, for example, can be short on resources whilst 'cash cows' burn too much money.

Viewed from a bottom-up perspective, another consequence of the organisational department structure can be a 'silo-thinking' when developing and executing marketing strategies (McDonald, 1992; Dibb and Simkin, 2000; Dibb, 2002). Business units, for example, can tend to develop their marketing strategies only with a perspective on their line of products rather than the company as a whole. Marketing departments, on the other hand, fail to communicate 'laterally' with other departments (Simkin, 1996, Dibb and Simkin, 2000). This lack of cross-functional thinking can thereby decrease organisational performance (Krohmer et al., 2002).

The Marketing Strategy Conferencing Approach, as outlined in the next section, addresses some of these impediments. In the following section, we introduce MSC, applied to two cases for the pharmaceutical, Schering Argentina.

Marketing Strategy Conferencing

Marketing Strategy Conferencing is an interactive-analytical approach to identify strategic marketing priorities. The objectives when applying the approach are twofold: first, it is designed to give insights into an efficient allocation of marketing-mix related resources through a consistent comparison of different marketing initiatives (analytical side). Second, MSC provides an effective discussion framework to arrive at a strategic consensus on marketing priorities (interactive side).

Multi-criteria Decision Modelling – The Analytical Side

The analytical side of the approach builds on a multi-criteria decision model. The building blocks of the model are individual marketing activities, such as different loyalty programs, customer service programs or advertising campaigns. Marketeers analyse each activity based on several benefit and risk dimensions as well as on monetary costs. The approach incorporates financial and non-financial benefits, such as the estimated impact of the activity on sales, its impact on market share, the extent to which the activity enhances corporate image or customer satisfaction.

A multi-attribute utility model then serves to collapse these multiple dimensions into a single risk-adjusted benefit value (Keeney and Raiffa, 1976). If the benefit criteria are constructed preference-independently – i.e. if the decision makers can judge the benefit of an activity on one criterion independently of the impact on another criterion – an additive aggregation of the benefit values is feasible. Following the assessments of all activities on all criteria and the weighting of the criteria to each other, the aggregated benefit value for each marketing activity can be calculated with the standard additive value model $V_i = \sum_j w_j v_{ij}$.

v_{ij} thereby represents the value associated with the consequence of option i on criterion j , and w_j represents the weight assigned to criterion j . The total value score for one option can be calculated as the sum of the weighted scores on each of the individual criteria. For a more detailed explanation of the technical details, see Phillips and Bana e Costa (2006).

Cost, benefit and risk criteria then serve to determine a 'marketing value-for-money triangle' for each activity, as outlined in Figure 1. The slope of the triangle indicates the resource efficiency of each activity: the steeper the slope, the better the benefit-cost ratio of a single activity.

Figure 1 – The Marketing Value-for-money Triangle

The marketing value-for-money of each activity now serves to prioritise strategic marketing activities. Those which lead to a high risk-adjusted benefit with comparatively low costs (steep triangle) should have investment priority over those with lower marketing value-for-money.

Strategy Conferencing – The Interactive Side

Although priorities might be analytically easy to set, a generation of commitment to related action might prove difficult. Addressing this problem, the decision modelling can facilitate effective vertical and horizontal communication across hierarchies and departments

in order to create strategic consensus on marketing priorities. An impartial facilitator guides a group of key decision makers through the evaluation process – a process, which Phillips (2006) calls decision conferencing.

Schuman and Rohrbaugh (1991) define decision conferences as ‘designed for groups that need to reach consensus about a complex, unstructured problem for which there is no ‘formula’ or objective solution...’ (p. 148/149). The objectives of a decision conference are thereby to create a shared understanding of the issues at stake, to develop a sense of common purpose and to gain commitment to a joint way forward (Phillips, 2006). Usually, the on-the-spot modelling is done within the framework of an intensive two-day meeting (McCartt and Rohrbaugh, 1995) or over a longer time period, which Phillips and Bana e Costa (2006) call ‘decision conferencing’.

As the primary purpose of a decision conference is often not to make decisions, but to explore strategic priorities and to contribute to strategic consensus, we call these meetings ‘Strategy Conferences’. In the two applications of MSC, outlined below, we carried out the approach within a time frame of several weeks. After a joint kick-off meeting with top-level management, smaller teams started with the collection of expert knowledge and data at the bottom of the hierarchy. This information – incorporated into the decision model – was then checked with the department heads and finally discussed on the next level, the Executive Board. As key stakeholders were engaged in developing the model, the system served to effectively combine the strategic vision of Schering Argentina’s top-level management with the operational knowledge of its middle managers.

Background to the Schering Cases

The pharmaceutical, Schering has a longstanding history in Argentina. The first subsidiary dates back to 1926. Focusing mainly on hormonal contraceptives, diagnostic imaging and special therapeutics for multiples sclerosis and oncology, Schering Argentina is above all producing and marketing pharmaceuticals. While originally the market prospects appeared promising in Argentina, over the last few decades, producers and suppliers of generic products have started to challenge Schering in its business segments. The economic crises of 2001/2002 in Argentina further increased the pressure on the company's departments to control costs and maximise the effectiveness of activities.

In 2005, a new CEO took office. Initiating strategic re-thinking within the company, he strove to restore the alignment of local marketing strategy and corporate strategy. In addition, this re-alignment aimed to prevent silo-thinking as the local business units had developed a great sense of autonomy over the years. One reason for this was the nature of the company's products and clients. A lack of cross-unit collaboration was the consequence.

During the research project MARA 2005 (Schaub and Schilling, 2005), we applied MSC for an analysis of Schering's customer service activities across all departments. A follow-up study in 2006, which the Fundación MARA performed, analysed a more diversified marketing portfolio, considering a larger budget. Table 2 provides an overview of these two applications of MSC at Schering Argentina.

	Schering Case 2005	Schering Case 2006
Scope	Prioritisation of selected customer service activities across all business units	Prioritisation of all marketing activities within the major business unit
Involved participants (approximation of overall hours engaged in meetings)	<ul style="list-style-type: none"> - CEO (8 h) - three business unit managers (45 h) - eight product managers (80 h) - one medical advisor (10 h) 	<ul style="list-style-type: none"> - CEO (6 h) - one business unit manager (42 h) - five product managers (90h) - two medical advisors (16 h) - four employees of other areas (32 h) - Furthermore, 40 medical advisors participated in an online survey to validate input data
Time frame	Following a two-week preparation, four analysts spent two months on client-site	Following one month of preparation, three analysts spent three months on client-site and an additional two weeks off-site.
Number of marketing options analysed	39 marketing activities in nine customer service investment areas	65 marketing activities in 14 marketing investment areas
Results	Potential efficiency increase of 101% in terms of marketing value-for-money Strategic insights: significant shift in customer service resources between business units would realise efficiency increases.	Potential efficiency increase of 118% in terms of marketing value-for-money. Strategic insights: Marketing resource allocation could be improved by overcoming previous (historic) resource commitments

Table 2 – Overview of Marketing Strategy Conferencing at Schering Argentina 2005 and 2006

The Modelling Process

For both cases, we constructed marketing activity portfolios, which consisted of a variety of investment areas with several investment options. In 2005, the areas included solely customer service activities. Currently performed service activities, as well as new activities, which we generated interactively with the Schering employees, served as investment options. In order to generate new activities, we asked the clients to imagine options without thinking of budget constraints, i.e. unaffected by associated costs, previous failures, technical or commercial feasibility. Figure 2 displays the portfolio of the Schering 2005 case. The black boxes at the bottom are the labels for the different investment areas, in this case, connected to several product lines. The shaded boxes above refer to the currently

performed marketing activities; the blank boxes to the possible new marketing activities. Modifications in the nurse service net for one business area or different advertising campaigns, are examples of these options.

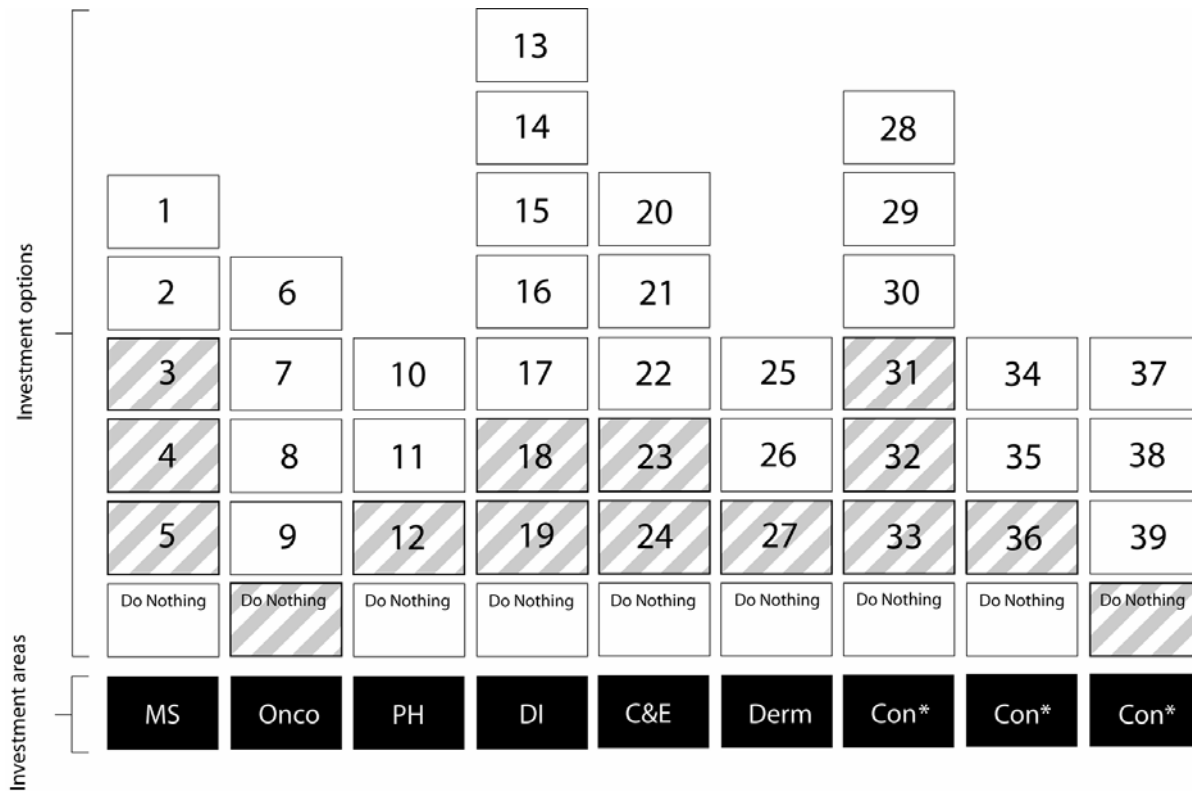

Figure 2 – Marketing Activities Attributed to Investment Areas of the Schering 2005
 (* refers to sanitised investment areas)

As the analysis proved useful, in 2006, Schering Argentina decided to repeat the approach within one business unit. In this follow-up case, we focused on the company's largest business unit and increased the scope of the analysis. This analysis included all activities that the business unit directed at the exterior and potential activities that the company could carry out. As a result, the budget in question increased to almost three times the amount we considered in 2005.

Having created the marketing activity portfolios, in both cases decision makers scored each option on each criterion. In 2005, for example, impact on sales volume, on the company image, and on ‘future value’ (long-term impact) served, besides monetary costs, as measurement criteria. Following the scoring, the weighting procedure allowed the company to calculate the marketing value-for-money for each activity. Figure 3 shows the creation of the marketing value-for-money triangle. Having carried out all assessments and assigned weights, the model calculated a marketing benefit value for each activity and then prioritised all activities according to their benefit-to-cost ratio.

Figure 3 – The Evaluation Process for a Marketing Activity, leading to an ‘Envelope’ (Marketing Value-for-money Triangles Stacked According to Decreasing Slope)

After calculating the marketing value-for-money for each activity, we could construct efficient marketing portfolios. Considering, for example, 39 options as analysed in 2005, more than 2.5 million combinations of different activities are feasible. All combinations of activities comprise a benefit and a cost figure. Figure 4 depicts these values as ‘envelopes’ for the 2005 and 2006 case. The grey-shaded areas contain all benefit-cost combinations of possible portfolios. The black dots on the upper frontier indicate the most efficient of these portfolios. They result for a certain budget in the highest marketing value-for-money.

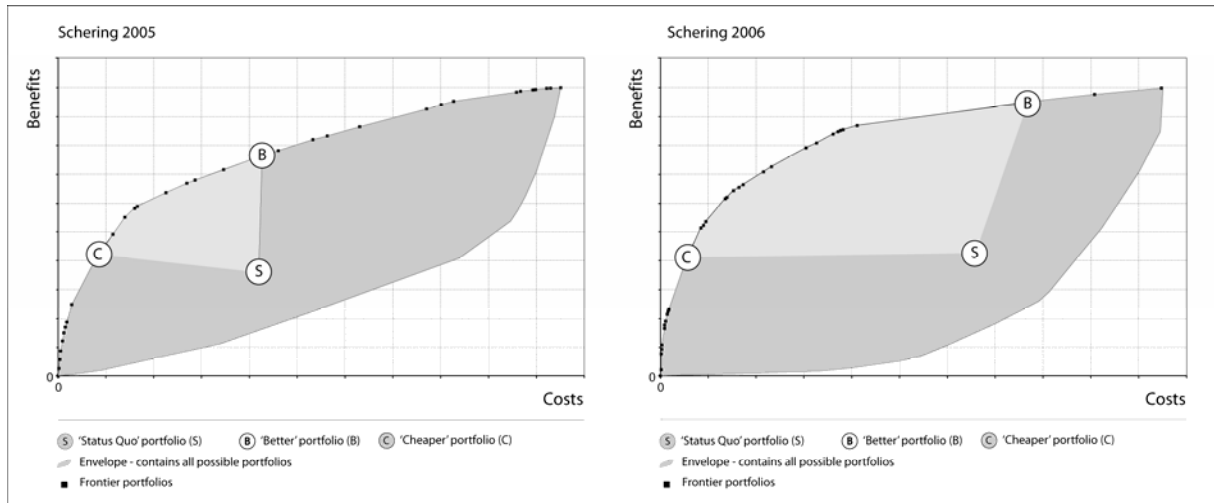

Figure 4 – Portfolio Values for Schering 2005 (left) and Schering 2006 (right). ‘S’ indicates the cost and benefit values for the current allocation of resources. ‘B’ refers to a better allocation of resources (similar costs, more benefits). ‘C’ refers to a cheaper allocation (similar benefits, less costs)

This display serves to identify potential improvements in resource efficiency compared to the status quo of the marketing budget distributions (‘S’ in Figure 4). Portfolio suggestions that result in similar or lower costs, but which provide substantially more benefit than the status quo are indicated with a ‘B’ in Figure 4. The point ‘C’ displays portfolios with a similar benefit level as the status quo, but with substantially reduced costs. In the 2005 case, we identified a 101% potential efficiency increase, in 2006 an improvement potential of 118%, compared to the status quo allocation. These efficiency increases can be realised by a re-allocation of resources – usually by omitting costly political projects, decreasing spending in some areas, whilst increasing spending in others. As the input data for the model relies on several estimations and assumptions, the potential efficiency increases are approximations. The approach aims not to exactly calculate the total marketing value-for-money for different portfolios, but rather to provide strategic insights into a better allocation of resources.

Whilst the envelopes in Figure 4 represent a top-level view on values of different portfolios, the included or excluded activities cannot be identified. To provide a further

discussion device, we developed a way to depict the individual efficiency of each marketing activity, as shown in Figure 5. We show each activity with its cost estimate and overall benefit value. Again, the axes reflect benefit and cost values, while the slope of the line connecting the origin and the activity now indicating the efficiency for that activity (Junghänel, 2005). Figure 5 on the left indicates status quo activities with black boxes, whilst displaying possible new activities with white boxes. Activities with the best marketing value-for-money ('High Efficiency' section), result in relative high benefits with lower costs. Using such visualisation, one can easily identify the sources of underperformance of the status quo allocation in 2005. As the status quo activities are distributed across the high, medium, and low efficiency areas, they cannot reach the efficiency level of the 'B' portfolio, as shown in Figure 5 on the right. In this case, the portfolio consists of activities rigidly chosen by moving down along the arrow like a 'wiper' with a fixed point in the origin towards the cost axis. In this display, the wiper stops at the budget constraint that 'separates' included from excluded activities. We did not include any of the activities below the shaded area (right graph) in the portfolio as their efficiency remained too low.

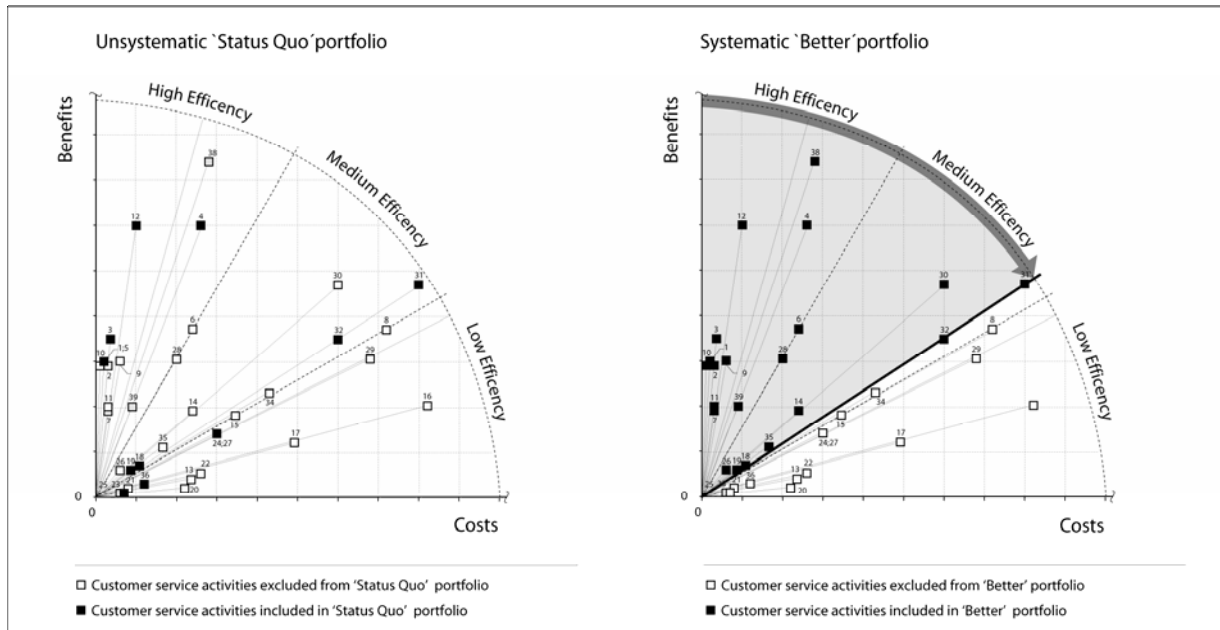

Figure 5 – ‘Wiper’ Display of the Marketing Value-for-money of the Customer Service Activities from the Schering Case 2005 (adopted from Junghänel, 2005)

Additionally, managers can use this illustration to identify activities whose efficiency ratio lies close to the ‘cut-off’ line. These activities are rather sensitive to changes in scores and weights or changes in the budget constraint. As such, they qualify for deeper analysis or further validation of input data. It is highly improbable, on the other hand, that a highly efficient activity will drop out of the proposed portfolio due to a slight change in scores or weights. Further analysis of these activities therefore is often not necessary. Phillips (1984) calls these just-enough models ‘requisite’ as – contrary to other management science models – they focus modelling effort on the most relevant parts of the analysis. A time efficient analysis, appropriate for the decision problem, is the result.

The two applications of Marketing Strategy Conferencing resulted in several insights for Schering Argentina. In 2005, the models gave insights into an efficient re-allocation of marketing resources from one of the business units to new and quick growing businesses. In 2006, results stimulated a critical analysis of historically established, thus little questioned

activities. Both results led to a significant re-allocation of resources. As the modelling results built on a transparent combination of data and judgment from Schering employees, the recommendation was owned by the managers and thus accepted and implemented. A sustainable strategic consensus on marketing priorities beyond departmental 'silo-thinking' was the consequence.

Conclusion

In this paper, we have introduced Marketing Strategy Conferencing as a flexible approach to set strategic marketing priorities and allocate resources accordingly. The analytical component of the system – built on a decision model – permits an analysis of the trade-offs between different types of strategic marketing initiatives. The interactive component of the approach – facilitated group meetings with on-the-spot model building and exploration – contributes to find strategic consensus on marketing activities and create commitment to action.

We designed the system to overcome some analytical, behavioural and organisational impediments to effective marketing resource allocation. First, the generative approach when creating new marketing activities helps to overcome incrementalism when deciding on marketing priorities. Second, the participatory decision process of Marketing Strategy Conferencing enhances communication across departments and hierarchies, thus contributes to create strategic consensus on marketing priorities. Third, by constructing a portfolio with consistent marketing value-for-money evaluations of each activity, managers can turn a departmental silo-perspective into holistic lateral thinking, enabling them to allocate resources company-wide as efficiently as possible.

When strategic consensus on marketing priorities is essential, Marketing Strategy Conferencing can be in particular appealing for the allocation of marketing resources. In contrast to the matrix-based approaches, MSC relies on customised rather than generic portfolios. More than twenty years ago, Wind et al (1983) wrote ‘... given that the conceptually more attractive customised [portfolio] models are more difficult to implement and require greater top management involvement, dominance of standardised portfolio models is likely to continue (p. 89).’ Due to the advance of information technology and simple graphical visualisation - essential for top-management applications - the time may be ripe to further enhance customised portfolio models and challenge the dominance of the matrix-based approaches.
